The sea provided an easy link between the regions of insular Southeast Asia and extended their rulers' potential to extend their military power considerably. The ships employed were capable of transferring large armies, including horses and elephants. These two illustrations, which were painted around the fifth century CE on the walls of a Buddhist cave at Ajanta in western India, show oared war boats carrying a fully equipped army across the sea. Although of Indian origin, the boats and armies depicted may not show much difference to the ones used in Southeast Asian naval warfare in the second half of the first millennium CE.

—Tilman Frasch

(Drawn by Tilman Frasch, after Dieter Schlingloff, *Guide to the Ajanta Paintings*, 1999)

Arab *dhaus*, the latter making their appearance in Southeast Asian waters around the ninth century CE. Their size enabled them to transport not only people and goods but also armies, including horses and elephants. The sea thus provided the basis for both trade and warfare in the archipelago.

The Malacca Straits formed a natural bottleneck for the shipping routes between the Bay of Bengal and China that could easily be controlled. This situation favored the emergence of Srivijaya as a major maritime kingdom of Southeast Asia. Epigraphic evidence suggests that the kingdom was centered at Palembang, thus controlling the southern portal of the straits. Dependencies were situated on Kalimantan Island, the eastern parts of Java Island, and on the Malay Peninsula. An inscription from the late seventh century, found in the vicinity of Palembang, gives an impression of Sri Vijaya's politics: "In April 682, the ruler (of Sri Vijaya) left the city with vessels and led an overland and maritime campaign, bringing home wealth, glory and power one month later." The target was Malayu, a region in central Sumatra famous for its gold deposits. Control of the mineral products—gold from Sumatra, tin from Malaya—added to the economic strength of Sri Vijaya, which was a mixture of policing the seas, enforced preferential trade, and occasionally outright piracy as well. However, given the extent of the area, it is debatable whether Sri Vijaya was a centralized empire of a federation of more or less

independent regional kingdoms cooperating in questions such as trade policies.

The only power capable of challenging Sri Vijaya's dominance in the western archipelago seems to have been the Sailendra rulers of central Java. Attempting to control local production centers and to tax trade just like their Sri Vijayan competitors eventually made them attack both the Khmer settlements in the Mekong Delta and the Cham kingdom in what is now Vietnam. For a brief period the Sailendras seem to have held sway over the Khmer lands before the capital was relocated to Angkor. Ultimately the Sailendras came into conflict with Sri Vijaya as well. In 990 CE King Dharmavamsa launched a successful naval campaign against Sri Vijaya that resulted in the conquest and occupation of its capital. However, Sri Vijaya's network of alliances was strong enough to compensate for the loss of its center. About two decades later the combined forces of Sri Vijaya retaliated with a naval expedition of their own that ended with the conquest of the Sailendran capital on Java. However, Sri Vijaya's triumph did not last long. In 1025 CE a South Indian king led an armada across the Bay of Bengal and apparently conquered Sri Vijaya again. This weakened the former empire to a point from which it did not recover, and ultimately other rulers of the regions seized the opportunity to establish trading centers of their own to participate in the trade flowing through the straits. Malacca and Temasek (Singapore) are the two best-known ex-

amples of this development. Apart from trade and war, religion was another area of intercourse. Indian Brahmins were regularly invited by Southeast Asian rulers to perform court rituals, compute time, or compose inscriptions. In turn, Buddhists from Southeast Asia were in contact with Indian centers of Buddhism, while monks from China occasionally studied at Buddhist centers in the archipelago. People in the archipelago were mainly followers of Mahayanist and Tantric schools of Buddhism, and the great stupa of Borobudur is an architectural witness to these traditions. But when Buddhism came under pressure in the centuries after circa 800 CE, the religion began to disappear from the archipelago, only to survive as a syncretist Hindu-Buddhism on the island of Bali. In a way, the Borobudur thus marked the apex and the turning point of Buddhism in insular Southeast Asia.

Relations between Kingdoms in India

Relations between kingdoms in ancient and medieval India were typically characterized by competition and conflict, accompanied by a good deal of intrigue and a dizzying array of constantly shifting alliances. The philosophy of governance that most rulers followed, as outlined in Kautilya's *Artha Shastra*, created what could be characterized as a situation of managed conflict in which fierce competition carried out by a variety of means, fair and foul, was presumed to be the

natural state of things. Western scholars have at times expressed horror at what some have seen as the amoral approach to governance found in the *Artha Shastra*, often comparing it, not unreasonably, to Machiavelli's *The Prince*. On behalf of the *Artha Shastra*, though—and, for that matter, Machiavelli—it could be argued that it is a practical, not a utopian, text and that a good ruler, with a realistic sense of the challenges facing him or her, may need to be prepared, in some situations, to behave ruthlessly. Kautilya, the purported author of the *Artha Shastra*, is said to have been the adviser to Chandragupta Maurya who, following Kautilya's advice, became the first king of the Maurya dynasty, quite a strong recommendation for this particular text.

The *Artha Shastra* depicts each king as being at the center of his own *mandala*, or circle of kings. If one could visualize one's kingdom as being at the center of a giant gaming board, the other kingdoms would represent the positions of one's fellow players. The kingdoms adjacent to one's own are regarded by Kautilya as one's enemies. The kingdoms just beyond these, in the next circle, are one's allies, and so on. The king is therefore visualized as being in the center of a series of concentric circles, with enemies and allies alternating in each successive circle. The gaming board has been set up, and its goals are quite simple: to survive and to expand one's

WARFARE OR ATHLETIC CONTEST?

The rules of warfare in ancient India were quite strict. Noncombatants were not to be targeted. But even when engaging with other warriors, one would be dishonored were one to violate certain limits. In the *Mahabharata*, for example, before the final battle is waged, both sides agree on rules of conduct. One cannot attack an opponent from behind or attack an opponent who is not armed. Fighting is to take place only during the day, and opponents cannot be attacked at night or while they are sleeping. It is even said that during the night, warriors from both sides ate, drank, and sang songs together, enjoying one another's company before retiring to bed to rest in preparation for the next day's conflict.

—Jeffery D. Long

kingdom at the expense of one's enemies and with the help of one's allies.

Clearly, Kautilya does not envision a utopian future in which there will be world peace. According to his rules in which one's neighbors are always, by default, one's enemies, then, if one were to be successful in eliminating one's enemies, expanding one's kingdom by the extent of a concentric circle, as it were, one's allies would then become one's enemies, and one's former enemies, two concentric circles away, would thereby become one's new allies, and the entire process would begin again. No king could ever fully trust another. Every enemy was a potential ally and every ally a potential enemy.

The closest thing to a situation of peace, on Kautilya's understanding, is one in which a single monarch manages to subdue all of his enemies and become the ruler of the entire territory: in practical terms, all of India. To become such a universal emperor, or *chakravartin*, was the goal of every king in ancient India. And only a few, such as Chandragupta Maurya, achieved it. But even the *chakravartin* must be able to maintain his empire and must beware of his feudatories—the lesser kings who owe him allegiance—forming alliances against him. This was often the fate that befell large polities in ancient India: a large empire, like that of the Mauryas or the Guptas, would arise but would later disintegrate into smaller kingdoms, each vying to become the next dominant power.

The vision outlined in the *Artha Shastra* is not a simplistic one in which kings are constantly at war with one another, in the overt sense. War can be waged in a variety of ways, and kings in ancient India competed with one another in many ways: through trade, the performance of elaborate Brahmanical rituals, or massive building projects. The competition among kings in ancient and medieval India played a role in the construction of some of the architectural and artistic wonders of that country. The building of temples was one way that a king could show that he was favored by the gods and thus deserved the title of *chakravartin*. Winning the royal competition was a matter not only of brute force but also of showing who could achieve the most. The competition among kings in the areas of art and architecture could perhaps be compared to

the twentieth-century space race between the United States and the Soviet Union: a competition for prestige as well as power.

One way for a king to assert his status as a contender for the title of *chakravartin* was the *ashvamedha*, or horse sacrifice. In this ancient Vedic ceremony, a horse would be released into the countryside (though carefully guided by its handlers). Wherever the horse would wander unchallenged, the king holding the ceremony could claim that land as his territory. Having the horse “wander” into the territory of a king that was one's ally and tributary was a way of reinforcing one's relationship of dominance over that king. And having the horse “wander” into the territory of an enemy amounted to a declaration of war. Typically, Indian kings did not hold this provocative (and also quite elaborate and costly) ceremony unless they were confident of their ability to back their (or rather, their horse's) claims with force.

This account of the situation of constant conflict among kings in ancient and medieval India, though, would be deceiving if one were to conclude from it that India was constantly wracked by warfare, with villagers being killed and the infrastructure of society facing repeated destruction. The caste system provided the check on the conflicts that were waged by kings upon one another, for outside the warrior, or *kshatriya*, caste, most Indians were not expected to engage in warfare. The honor code among *kshatriyas*, as it is depicted in the *Dharma Shastras*, or Legal Texts, and epic literature, such as the *Ramayana* and the *Mahabharata*, was quite strict. Noncombatants were not targeted in battle. The population of a kingdom and its infrastructure were the prize to be won, not the enemy to be destroyed. That distinction belonged only to the rival king and his warriors.

■ Introduction: Inner Eurasian Wars

To discuss the conflicts in Inner Eurasia, it is useful to divide the region into three parts:

- 1) The eastern steppe, including the grasslands of Inner Mongolia, Mongolia, and the Altai Mountains as well as an indeterminate region to the west of the Altai.
- 2) Central Asia, from the western reaches of China's Gansu Province, the Tarim Basin; the oasis cities and deserts of the region of the Oxus (Amu Darya) west to the Caspian Sea; and the grassland north of this area.
- 3) The western steppe, including the grasslands north of the Caspian Sea, the North Caucasus, the Pontic (Black Sea) steppe to the Danube River, and the Pannonian (Hungarian) plain.

This is a vast area, but communication and travel for well-armed groups could take place, and peoples could migrate from the eastern to the western steppes in several decades. This migration of peoples allows a somewhat unified historical narrative: there were connections between the regions.

In the East, before our period, the Xiongnu created a great steppe empire, which fought for centuries against the Han dynasty. The Xiongnu split into northern and southern empires in 48 CE, with the Southern Xiongnu allied with the Chinese. The Northern Xiongnu were defeated by the Chinese in 89 CE and migrated west. According to some historians, their descendants reappeared on the Black Sea steppe as the Huns, where they drove the Goths into the Roman empire and started the Great Movement of Peoples that brought down the western Roman empire in the fifth century.

The Hephthalites (White Huns, probably not related to the Xiongnu Huns) may have been driven south by the Huns from their pastures on the steppe north of central Asia to attack the Sassanian Persians in the fifth and sixth centuries. Defeated by the Persians, the Hephthalites moved south into India, where they have been credited with helping to bring down the Gupta empire.

Meanwhile, the Southern Xiongnu remained allied with the Han dynasty until the fall of the Jin dynasty (304) when they invaded northern China and set up a dynasty known as the Northern Han. Very soon, other steppe peoples moved on the northern Chinese plain, drawn by the vacuum created by the fall of the Jin. Sixteen different groups of steppe "barbarians" fought savage wars for supremacy in northern China until the Toba, who may have been of Xienpei stock, defeated all the rest. In 386, they established the Northern Wei dynasty and, during the next century and a half, assimilated Chinese culture and fought other steppe peoples who attempted to raid northern China.

In a protracted contest, the Toba defeated the Juan Juan, who had gained supremacy in the eastern steppe. After their defeat, the Juan Juan migrated west. Some historians think that they are the same as the Avars, who arrived on the Pannonian Plain in the 560s, where they raided and harassed the West Europeans and the Byzantine empire until they were conquered in the 790s by the armies of Charlemagne.

Meanwhile, in the eastern steppe, the Gokturks, from their base in Mongolia, created the first Turk empire (552) in the vacuum left by the collapse of the Juan Juan. The first Turk empire soon conquered all the peoples on the eastern steppe and collected tribute from the trading oasis cities in the Tarim Basin and into the Oxus region. The first Turk empire split (581) into an eastern and a western Turk empire, but both of them were destroyed by the rising power of the Tang dynasty by 630.

After the collapse of the western Turk empire, some of the western Turks moved farther west, where they participated in the events leading to the founding of another Turkish empire, that of the Khazars in the first third of the seventh century. The Khazar empire, whose capital Itil was located in the delta of the Volga River, was probably the longest lasting of these steppe empires, enduring nearly three and a half centuries (ca. 625–965). The Khazars dominated the western steppe from the mouth of the Danube River to the grasslands north of the Aral Sea. The

Khazars were very warlike and fought the expanding Muslim Arab empire to a standstill in the Caucasus in the mid-seventh century. The Khazars were usually allied with the Byzantine empire, and the ruling families of the two empires intermarried. The prosperity of the Khazars was based on the tributes they extracted from their subjects on the steppe as well as from the East European forest people they dominated and taxes from the international trade that they controlled. The Khazars were unique in that they were the only great power to convert to Judaism.

The Khazar began to decline in the ninth century, when Pecheneg Turks from the steppe north of central Asia began to invade the steppe north of the Black Sea. Finally, in 965, Viking Rus who had conquered Kiev, an erstwhile Khazar stronghold, destroyed the Khazar capital and with it the Khazar empire.

Back on the eastern steppe, Gokturks founded a second Turk empire (683) that dominated Mongolia and collected tribute from peoples on the northern periphery of the Chinese empire. This empire lasted 51 years, until the Uighur, a subject people, overthrew the second Turk empire (733).

The Uighur, who became a loyal ally of the Tang dynasty, established their empire over the same territory that the second Turk empire had occupied and collected tribute from their new subject peoples. During An Lushan's Rebellion, 755–763, the Uighurs intervened to support the Tang dynasty, during which they occupied and thoroughly sacked the Tang eastern capital, Luoyang. After the rebellion, China was required to pay tribute to the Uighurs, who occupied the oasis cities of the Tarim Basin. The Uighurs were unique in that they were the only great power to adopt Manichaeism as a state religion. Erstwhile Uighur subjects destroyed the Uighur empire in 840.

At the beginning of the tenth century the Tang dynasty collapsed, giving way to half a century during which China was divided and convulsed by warfare among a multitude of local warlords (the Period of Ten Kingdoms and Five Dynasties [907–960]). During this period of chaos another steppe people, the Khitan, emerged to seize part of northern China, and although in 960 another strong Chinese dynasty, the Song, reuni-

fied China (960), it was unable to wrest back the slice of northern China occupied by the Khitan, who established themselves as the Liao dynasty.

Kiev, the Pechenegs, and the Khazars

During the early and mid-tenth century CE, a large-scale three-way conflict developed in the Pontic steppes (grasslands north of the Black Sea) between the Khazar Khaganate, encroaching Pecheneg hordes, and the nascent principalities of the Rus. The Pecheneg invasion of the region in the late ninth century triggered a series of migrations that caused the Khazars to lose their main northern allies, the Magyars. By the early tenth century the Khazar-dominated Saltovo-Mayaki had collapsed, and at some point between 880 and 920 the Khazars lost control over the Dnieper Valley, including the vital stronghold of Sambata (Kiev), which fell to the Rus warlord Oleg. Khazar power was reduced to the region of the lower Don Valley, the Volga Delta, the Taman Peninsula, and parts of the Crimea and Caucasus regions. Within a short time the Pecheneg territories abutted the growing Kievan Rus, and the two groups came into increasing conflict.

The Khazars adopted a somewhat ambivalent policy toward the Rus. Conflict often broke out, particularly after the fall of Kiev. In 910 a massive Viking expedition, either originating in or allied with the Rus princes, was attacked and destroyed by a Khazar army after having pillaged Muslim states around the Caspian Sea. Around 940, a Rus warlord identified in Khazar sources as HLGW (possibly the same Oleg who conquered Kiev) was defeated by the Khazar general Pesakh after the former attempted to wrest the eastern Crimea and the Taman Peninsula from Khazar control. Yet there is evidence that the Khazars saw seagoing Rus and Viking

pirates as useful allies of convenience to be used against Byzantine interests around the Black Sea, and the Khazars may have played a political balancing act between permitting Vikings passage into the Caspian Sea to raid their Muslim neighbors and preventing such access when it was expedient to do so.

The Byzantine empire, keen to protect its economic and strategic interests in the region, played the three powers against each other. Having borne the brunt of a number of Rus incursions, Constantinople had initially sought to support and ally with the Khazars as a bulwark against Rus and Pecheneg attacks. By the tenth century, Byzantine policy had shifted, and the empire began sponsoring uprisings among the Khazar Khaganate's vassals (uprisings that may have been supplemented by Byzantine-hired Pecheneg aid). Emperor Constantine VII Porphyrogenitus identified the Pechenegs as the dominant steppe power and potentially valuable allies in his book *De Administrando Imperio*, written around 950. Increasingly, the Byzantine empire sought alliances with the Pechenegs against both the Rus and the Khazars.

The destruction of Khazar imperial power around 969 by the Rus prince Svyatoslav of Kiev, who sacked the Khazar city of Sarkel and the capital of Atil, created a power vacuum in the Pontic region and changed the dynamic of political alliances. The Byzantines soon changed their policy and allied with Svyatoslav against the Danube Bulgars, but when Svyatoslav's demands for territorial and economic concessions proved too burdensome, Emperor John I Tzimiskes had no qualms about realigning his empire with the Pechenegs, who ambushed and killed Svyatoslav in 972.

One consequence of the disappearance of the Khazars was that the steppe trade routes, which had been stable for centuries under what some scholars call the Pax Khazarica, became unsafe and virtually collapsed. The virtually simultaneous fragmentation of the Frankish, Abbasid, and Tang Chinese empires meant that trans-Eurasian trade declined, causing many local economies to disintegrate and further feeding the chaotic conditions.

After Svyatoslav's death, Rus power in the steppe region generally declined as Rus politics

➤ SVYATOSLAV'S VAULTING AMBITION

The Rus prince Svyatoslav I of Kiev provides a perfect illustration for the shifting politics of the period. He defeated the Volga Bulgars in 965, reducing them to vassaldom and bringing the upper Volga under Rus control. Rallying the Khazars' Slavic vassals against their overlords, he invaded the Khazar Khaganate and destroyed its capital around 969. Immediately thereafter he allied with the Byzantine empire, formerly the enemy of Kiev, in a joint expedition against the Bulgarian khanate on the Danube, most of which he conquered. Possibly to break with the past and signal the genesis of a new empire, he moved his capital to Pereyaslavets, in modern-day Bulgaria, around 970, leaving his mother Olga as regent in Kiev. After a dispute over the spoils of battle he turned on his Byzantine allies, marching as far as Adrianople before he was defeated by the Byzantine emperor John and agreed to return to his Kievan territories. John then allied with the Pechenegs, whose khan, Kurya, ambushed and killed Svyatoslav in 972 on the latter's return journey home. According to Russian chroniclers, the Pecheneg khan so respected Svyatoslav's fighting prowess that he had the Kievan prince's skull gilded and made into a drinking goblet.

—Brian Gottesman

fell to infighting and lost most of Svyatoslav's conquests. Over the succeeding decades, Pecheneg tribes sometimes formed alliances with one another or with Rus states, sometimes united briefly to make war on the Rus, and sometimes turned on one another. It was not uncommon to find both Rus and Pecheneg forces fighting on both sides of the same battle.

With the conversion of the Rus to Christianity under Vladimir in 988, Byzantine policy swung again toward alliance with Kiev and its sister and successor states against the Pechenegs (some, but by no means all, of whom also adopted Christianity). A joint Byzantine-Rus invasion destroyed a Khazar successor state in the Crimea in 1016, and while Khazar politics may have survived in the Caucasus for some time thereafter, they would play no further role in international affairs.

The Rus, however, remained unable to break the Pecheneg hold over the Pontic steppes. Notwithstanding their inability or unwillingness to form a single unified kingdom, the Pechenegs remained the dominant military force in the region for almost a century, until in the mid-eleventh century they were defeated and forced west by the Kipchaks (Cumans). Again sensing the shifting balance of power and continuing their tradition of allying with far-off barbarians against those closer at hand, the Byzantines allied with the Kipchaks to crush the last remnant of Pecheneg might at the Battle of Levounion in 1091 and the Battle of Beroia in 1122. The Kipchaks would dominate the steppes and fill the vacuum of power until the Mongol invasions of the thirteenth century.

The Turks, Uighurs, and Tibetans and the Tang/Abassid Contest for Central Asia

In 600 CE central Asia continued its strategic and economic importance. The trade routes running through central Asia were sources of great wealth, and China and the Arabs as well as the nomadic groups on the periphery fought to control it. In the late sixth century CE China emerged from more than 300 years of fragmentation when it was united by the Sui dynasty (581–618). However, Sui policy caused widespread revolts, and the Sui fell to the Tang dynasty (618–907). Tang interest in the world outside China, especially to the west, made central Asia a focal point. In the Middle East the Arab Umayyad caliphate also turned toward central Asia. Both empires saw the steppe nomads, including the eastern and western Turks, Uighurs, and Tibetans, as pawns to further their own political agendas.

In the mid-seventh century China found itself threatened by newly emerging nomadic groups. When an attempt to divide the eastern Turks' forces failed, the Chinese turned to tribute to control the nomads. The eastern Turks grew rich from Chinese payments but soon fell under Chinese control. China resettled them in the Ordos, but the Turks rebelled and reestablished their khanate, which dominated the Mongolian steppes for the next 50 years.

➤ KAO XIENQI—THE TANG'S KOREAN PROCONSUL IN CENTRAL ASIA

Little is known about the early life of Kao Xienqi, a Chinese general of Korean origin, but by 747 he had distinguished himself enough to be awarded the titles of “Assistant Protector-General of the Pacified West” and “General Commissar for the Troops and Horses of the Four Garrisons.” With an army of 10,000 he traveled across central Asia, finally defeating the Tibetans in the Pamirs. This gave China control over the important Pamir and Wakhan regions and the Tarim Basin. Kao was made the governor of four military garrisons for his victory. However, his overbearing attitude and his policies against Tashkent angered regional leaders. Together with the prince of

Tashkent, they allied with the Arabs against the Chinese.

In 751 Kao received intelligence that a large Arab army including Tibetan and Turkish troops was headed toward the Chinese frontier. The Arab army, led by Ziyad ibn-Salih, met Kao's forces near the present-day city of Jambul, Kazakhstan, on the Talas River. The battle continued for five days, during which time the Turkic forces fighting with the Chinese changed sides. The Chinese were forced to retreat through mountain passes choked with refugees fleeing the battle. Kao escaped, but thousands of his men were captured and taken as prisoners to Samarqand.

—Rebecca Wendelken

CENTRAL ASIA, 618–907

Between 647 and 679 another Turkic group on the northwestern frontier, the Uighurs, came under the Chinese *jimi fuzhou* system. They retained their traditional leaders but in reality were subjects of the Tang. The Uighurs quickly settled and became dependent on trading horses for Chinese silk. They occasionally rebelled, but for the most part the Uighurs allied with China and formed China's primarily frontier support forces. When internal fighting destroyed the eastern Turkic khanate in the 740s, the Ordos fell to the Uighurs (744–840).

The western Turks in Transoxiana also formed a state, but it crumbled shortly after 630. Rather than ally with the eastern Turks in Mongolia, some groups, including the Türgesh and Karluk, remained independent. Together they fought to drive out the Arabs but were unsuccessful. In the mid-seventh century a new group, the Tibetans, began expanding into central Asia. They allied with the advancing Umayyads, and soon the Tibetans controlled the southern Silk Roads and most of the Hexi corridor. They re-

mained in control from the seventh century to the ninth century. Despite the marriage of a Chinese princess to the Tibetan king in 710, relations between China and Tibet were contentious. They signed a peace treaty and established a border but continued fighting over the kingdom of Bru-sha in northwestern Tibet that controlled the overland trade between central Asia and India.

In 750 the Abbasids overthrew the Umayyads, and the capital of the Islamic world moved to Baghdad. This shift increased the importance of central Asia, no longer the periphery of the Arab world but now the center. In the spring of 751 the Chinese and Abbasids clashed for the first and last time. A Chinese force marched into Ferghana (in central Asia) and proclaimed Chinese suzerainty. In July a combined Chinese and Karluk Türk force led by Kao Xienqi met an Arab army supported by Tibetans and Uighurs at the Talas River. The Karluks defected to the Arab side, and the Chinese were defeated. The battle marked the beginning of major changes in the central Asian steppes. It ended Chinese involvement west of

THE BATTLE OF TALAS AND THE TRANSMISSION OF PAPER MANUFACTURING

According to Thaalibi, the eleventh-century Arab author of *The Book of Curious and Entertaining Information*, the central Asian city of Samarqand was famous for papermaking in the medieval world. He traced the origins of paper manufacturing in Samarqand back to the Battle of Talas in 751. Fought between Muslim forces led by the Arab commander Ziyad ibn Salih and Tang Chinese forces under the command of General Gao Xianzhi, the Battle of Talas resulted in a reconfiguration of power in central Asia. The Chinese defeat, even though it merited little attention among Chinese and Arab historians at the time, came to be regarded in later centuries as the beginning of the Chinese withdrawal from central Asia and the beginning of Muslim domination. Following Thaalibi, later historians also associated the battle with the transmission of papermaking.

Relying on a book written at least one century after the events, Thaalibi wrote that Muslim soldiers took captured Chinese papermakers to headquarters in Samarqand, where the Chinese prisoners of war transmitted the skill of papermaking to their captors. Nowadays historians regard Thaalibi's account as factually inaccurate. Chinese accounts of the Battle of Talas describe the capture of various Chinese artisans such as goldsmiths and silversmiths during the battle but

make no mention of papermakers. Moreover, archaeological evidence demonstrates that paper was already circulating in the region of Samarqand before 751. The papers discovered at a cave near Mount Mugh (now Tajikistan), where Destavich, lord of Samarqand, had sought refuge in the early 720s, date back to the early eighth century and were probably manufactured locally.

Despite its factual inaccuracy, Thaalibi's story captures an important moment in the history of the transmission of paper technology. After the Battle of Talas and with the establishment of the Abbasid dynasty around the same time, the rulers of the Muslim empire began to focus on the eastern part of their domains. The incorporation of central Asian domains sped up the transmission of papermaking across central and West Asia. The Battle of Talas thus demarcated the assimilation and rapid expansion of papermaking in the Muslim empire even though it did not coincide with the first transmission of the skill to central Asia.

the Pamirs. It also stopped the eastern expansion of the Abbasids and made Tibet a regional power. The Turkic world became permanently divided as the western Turks settled and were absorbed into the Islamic cultural sphere. The eastern Turks continued their nomadic traditions, eventually converting to Buddhism.

The battle did not stop the fighting, however. China continued to have diplomatic relations and military conflicts with the Tibetans, Uighurs, and Turks. During the An Lushan Rebellion (755–763), which nearly brought down China's Tang dynasty, the Uighurs honored their borders, but the Tibetans took advantage of the situation to invade Chinese territory. In 783 after a series of treaties, China recognized Tibetan occupation of former Chinese holdings in central Asia.

Three years later the Tibetans occupied the Silk Roads town of Dunhuang, controlling it until 848. In 814 Tibet was defeated by the Abbasids near Karakoram, after which their power in central Asia declined. By 866 political and religious infighting brought an end to the Tibetan empire.

China's alliances with the Uighurs continued to help stabilize the frontier. With the fall of Tibet many important cities along the Silk Roads, including Dunhuang, became dependencies of the Uighurs. However, the Uighur empire was nearing its end. In 840 a Uighur general led a force of 100,000 western Turks against the Uighur ruler. The empire collapsed, and the Uighur population disbursed, many migrating to the west.

Despite the resulting power vacuum in the steppes, China made the decision not to reclaim its former possessions in central Asia. The Tang dynasty was experiencing rebellions and mutinies of its own. The dynasty fell in the early tenth century, ending at least momentarily the struggle over central Asia.

■ Introduction: Early Medieval West European Wars, 650–1000

Western Europe in 650 was divided into numerous kingdoms and other polities, and war between them was frequent. Since the collapse of Roman authority in the fifth century, the society and culture of western Europe had become increasingly militarized, and armed bands were frequent. The Visigoths had almost completely united Spain, while Italy was the arena for protracted conflict between Lombard forces, which had invaded the country in the late sixth century, and the Byzantine authority, which had been imposed on an unreceptive land in the mid-sixth century.

Gaul (France) and Germany were ruled by Merovingian descendants of Clovis, the fifth-century unifier of the Franks. These descendants, each a king in his area, were almost constantly at war with each other except when a single Merovingian kingdom could briefly impose its rule on the rest. In Britain, Celtic chieftains warred with advancing Anglo-Saxons, who were themselves divided into numerous little “kingdoms.”

In the late seventh century, the Arab Muslim juggernaut swept across North Africa and in the second decade of the eighth century destroyed the Visigothic kingdom and added Spain to the Muslim world.

In the early decades of the eighth century, Charles Martel united the Frankish kingdoms under his rule and stopped Muslim Arab expansion into western Europe at the Battle of Tours

(732). Charles’s son, Pepin, defeated the Lombards in Italy (751) and was anointed King of the Franks by the Pope. Pepin’s son Charles, called the Great (Charlemagne), was proclaimed (West) Roman emperor in 800 CE and ruled an empire that extended from northern Spain to beyond the Elbe River in central Europe. Charles fought many wars, chief of which were the conflict against the Spanish Muslims in northern Spain, a 30-year series of wars to subdue the pagan Saxons in northern Germany, and the contest in which he destroyed the kingdom of the Avars in Pannonia (Hungary). On his death in 814, a 3-year civil war among his sons split Charlemagne’s empire into three successor states, which resumed the endemic warfare that had characterized the Frankish kingdoms before their unification by Charles Martel. The western Frankish kingdom became France, while the eastern one became Germany.

Most of the ninth century and much of the tenth century in western Europe were characterized by endemic violence in which a multitude of nobles with armed followings fought each other for land and power. These were localized wars because, in these centuries, the central authorities of large kingdoms had atrophied. In these centuries, three invasive groups threatened western Europe:

- 1) The Muslim states in North Africa and Spain. In the ninth century, the Aghlabid emirate of

Ifriqiya (Tunisia) conquered Sicily and raided southern Italy, while the Spanish Umayyad caliphate seized the Mediterranean coast of France and sent raiders deep into southern France and the Alpine country.

- 2) The Scandinavian Vikings. These raiders terrorized the Atlantic littoral and islands, looting cities and enslaving populations. In the forestlands of eastern Europe, they established strong points, such as Strya Ladoga and Gorodishe, from which they preyed on surrounding populations and exacted slaves and tributes. Eventually, they established kingdoms in Ireland, England, and Russia and seized the province of Normandy in France.
- 3) The Magyars, who migrated from the steppe north of the Black Sea to Pannonia (Hungary) at the end of the ninth century and terrorized Germany, France, Italy, and the Balkans with raids in the first half of the tenth century, until the German king Otto the Great stopped them at the Battle of Lechfeld.

Wars of Charlemagne

During his 46-year reign between 768 and 814, Charlemagne undertook an unprecedented 54

military campaigns, greatly expanding the territory of the Frankish kingdom. And even though the Frankish army was relatively small compared to armies of the Classical Period (modern estimates vary from 5,000 to 35,000 men, excluding attendants), it was sufficient to carve out the largest state that western Europe had seen since the fall of the western Roman empire some 300 years earlier. His impressive military and political achievements even won him the title of “emperor of the Holy Romans” from the papacy on Christmas Day 800 CE.

Charlemagne’s campaigns took him to many areas in Europe. In 773 he led his army into Italy, crushing the Lombards and crowning his son king of Italy. Four years later Charlemagne crossed the Pyrenees into northern Spain. This campaign proved disappointing. Despite the annihilation of his rear guard at Roncesvalles by the Basques in 778, Charlemagne and his successors were successful in eventually establishing the Spanish March, a string of fortifications in Catalonia that served as a defensive bulwark against Muslim raiding and a future base of operations for the Christian reconquest of Spain in the eleventh century.

Charlemagne was more successful in his eastern campaigns into Germany. In 787 he invaded Bavaria and brought that region under his rule. In 790 his Frankish armies marched east along the Danube and met and utterly eradicated the Avar empire in the Balkans, seizing wealth accumulated in two centuries of raiding and adding it to his own treasury. Perhaps Charlemagne’s greatest success came in Frisia and Saxony, a region in northern Germany between the Rhine

► EQUIPPING CHARLEMAGNE’S ARMY

The composition and equipment of Charlemagne’s army was continuously evolving. Initially, the Carolingian Army was composed mostly of infantry, but as campaigning took him farther and farther from his base in Austrasia, Charlemagne soon relied increasingly on mounted troops rather than infantry. His numerous capitularies point to the raised status of cavalry. During 792–793 he issued regulations requiring vassals to have a horse, shield, lance, sword, dagger, bow, quiver, and arrows. In other

royal decrees wealthier nobles were ordered to come to war wearing mail and were asked to bring rations for three months of service and clothing for six. Furthermore, these greater magnates were to make certain that their own vassals came on campaign with a standardized panoply consisting of shield, spear, bow, and 12 arrows. Even attendants were required to be armed with bows.

—Brian Todd Carey

CAROLINGIAN EMPIRE AND CHARLEMAGNE'S WARS, CIRCA 800

and Elbe rivers. Beginning in 772 Charlemagne set his sights on the conquest and conversion of these regions, but resistance was fierce (Charlemagne campaigned in Saxony in 772, 785, 792–793, and 798–803). It was not until 804, after 18 annual campaigns, that Saxony was finally pacified and added to the Carolingian domain.

Charlemagne never developed a regular standing army; instead, he relied on feudal levies to raise his forces. It did not take the emperor

long to assimilate new regions into his military machine. Just two years after bringing Saxony into the kingdom, Charlemagne created a sliding scale of military contributions, ordering five Saxon vassals to equip a sixth to campaign in Spain and two to equip a third for Bohemia, while all were required to campaign against regional threats. In 807 he issued a capitulary decreeing that all nobles in the realm holding a benefice (a lease of land) were obligated to

Charlemagne leads his troops during the Spanish March, fourteenth century manuscript. Charlemagne's troops were principally horsemen—the Frankish army relied heavily on cavalry especially after the Battle of Poitiers (Tours) in 732. (The Art Archive/Corbis)

military service. If a noble failed to muster for war, he risked the confiscation of his estate. Charlemagne perfected this system to the point where he could raise several annual levies and conduct operations on multiple fronts, including Germany, Bohemia, Brittany, and Spain.

Charlemagne's military success was not founded on the decisive engagement; indeed, history records him present at only three battles during his lengthy reign. The Carolingian emperor's success was instead based on a well-trained and experienced feudal fighting force wearing down the enemy through a strategy of attrition and the ability to raise several armies for annual campaigns in different regions. He also recognized the impending threat to his empire, building and garrisoning forts along his borders with the Muslims, Danes, and Slavs. He even went so far as to try to maintain his superiority in military equipment by threatening the forfeiture of all property to anyone selling mail

hauberks to foreigners and death to any who exported Carolingian swords out of the country.

Finally, perhaps Charlemagne's greatest military legacy was his emphasis on cavalry as an instrument of strategic mobility. And although the stirrup-stabilized lancer, probably present in limited numbers during Charlemagne's reign, did not revolutionize battle tactics in the late eighth and early ninth centuries, heavy cavalry's importance as the centerpiece of the Carolingian tactical system was a harbinger of how war would be made in the later medieval period.

Viking Raids

By far the most devastating and widespread attacks in Europe during the ninth and tenth centuries came from the Vikings of Scandinavia. The Vikings were a Germanic people based in Norway, Sweden, and Denmark, and their movements constitute the final wave of Indo-European migration. Warriors, traders, superb shipbuilders, and sailors, the Vikings pushed south from their homeland in their trademark longships and attacked the whole of Europe. Norwegian Vikings moved into Ireland and western England, while the Danes attacked eastern England, Frisia, and the Rhineland and navigated rivers to enter western Carolingian territories. Swedish Vikings controlled the Baltic Sea and pushed into Slavic areas in eastern Europe. Moving into northwestern Russia, the Swedes sailed up and down that region's rivers to Novgorod and Kiev and established fortified ports in these areas, ultimately influencing the development of early Russian civilization. Sailing down the Dnieper and Don rivers to the Black Sea, they made contact with

the Byzantine empire as both traders and raiders, and the Byzantine emperor even hired Russo-Swedish Vikings, the Varangians, as his personal bodyguards. The Vikings also sailed west and settled in the Faroes, Iceland, Greenland, and, for a short time, North America.

The Viking age of expansion and conquest had its beginnings in a culture permissive of ship-based raiding. The shore raid, or *strandbogg*, was an age-old Viking tradition, one where warriors would beach their longship, round up cattle and sheep, and then sail off. This form of medieval livestock rustling was even done in Scandinavia itself until it was outlawed by the rise of centralized monarchies in the ninth and tenth centuries, forcing the *strandbogg* into foreign waters. Raids against continental Europe and the British Isles brought more opportunities, with Vikings returning from their seasonal raids with young women and healthy youths for the thriving slave trade.

Early Viking raids were usually carried out in the summer, with Scandinavian warriors sacking coastal villages and towns, destroying churches and monasteries, and easily defeating local, mostly infantry-based militias. In the first decades of the ninth century Viking raiding involved small numbers of ships and was mostly directed against Europe's coastline. But the death of Charlemagne in 814 and the chaos that followed under the weak rule of his son and successor Louis the Pious offered an attractive target for Viking marauders. As news spread of the wealth and vulnerability of the Frankish interior, Vikings appeared in greater numbers. By the 830s larger Danish fleets were threatening England as well with seasonal raids. During the winter of 840–841 the Norwegian Vikings switched from seasonal raids to wintering in enemy territory, staying for the first time on a small island off the coast of Ireland. When the Carolingian empire erupted into civil war at the death of Louis the Pious in 843, Vikings set up permanent bases at the mouth of the Loire and Seine rivers and then launched raids inland, sometimes on ships, sometimes on captured horses.

The size of Viking armies also varied depending on the period. Early-ninth-century raids consisted of a few longships and maybe 100 warriors.

Carved stone grave marker outside the ruins of Lindisfarne Priory depicts a row of Viking raiders. Viking warriors devastated the Anglo-Saxon monastery in 793 CE. (Ted Spiegel/Corbis)

But by 865 Viking activity in western Europe was concentrated in the Great Army made up of fleets of hundreds of ships carrying thousands of Viking warriors and led by several Scandinavian kings. Between 865 and 879 and again between 892 and 896 the Great Army plundered England, with the Danes occupying an area known as Danelaw in northeastern England. Accepting Christianity, the Danes were eventually assimilated into the larger Anglo-Saxon kingdom, giving their greatest warriors, the *huscarles*, to the English king as bodyguards. On the continent, the Great Army devastated Flanders, raided deep into the Rhine Valley, and even besieged Paris in the winter of 885–886 with perhaps as many as 40,000 men and 700 ships, although probably the numbers involved were much smaller.

But as widespread as the Viking raids and invasions were, the Vikings were, in fact, not particularly good at winning battles. Many of their victories came from attacking soft, undefended targets such as churches and monasteries well stocked with ecclesiastical treasures and sacramental wine. When regional armies finally organized and offered determined resistance in the late ninth century, the fortunes of the Vikings changed. In England the Anglo-Saxon king Alfred the Great (r. 871–899) built walls around his towns, creating *burhs*, and founded the first English navy in 875 to intercept Danish fleets at sea.

THE VIKING LONGSHIP

The primary instrument of Scandinavian overseas aggression was the longship. Long, narrow-keeled and flat-bottomed vessels with beautifully carved arched prows, the first longships carried around 35 warriors. They were made of oak using clinker construction (overlapping planks held together with clinch bolts) with a mast amidships and one bank of oars on each side. Controlled with two steering oars, these vessels had shallow drafts, making it possible for them to navigate up rivers and along coastlines, giving the Vikings unprecedented strategic mobility. The *Gokstad* ship, built in the second half of the ninth century, was more than 76 feet long and 12 feet wide and drew less than 34 inches of water, giving it the ability to sail up rivers and estuaries into shallow waters only 3 feet deep. Longships were also easy to beach and portage over short distances using rollers and manpower.

—Brian Todd Carey

In France, cities were walled (or if dilapidated by neglect were rewalled), and fortified bridges were constructed across major rivers to close access to the interior. Unaccustomed to fortifications, the Vikings usually moved on. Moreover, when battle was offered by the defenders of a realm, the Vikings often preferred negotiations or withdrawal to a set-piece engagement.

The last great Viking invasion took place in 1066 when a massive Norwegian invasion fleet set sail for England to challenge the new Anglo-Saxon king, Harold Godwinson, for the English Crown. Although Norwegian king Harald Hardrada would be ultimately defeated by Godwinson at the Battle of Stamford Bridge, another Viking offspring, Duke William of Normandy, would successfully invade England using Viking-designed warships and transports, defeating Godwinson at the Battle of Hastings and ending the Viking age.

Anglo-Saxon Wars, 700–1000 CE

The period 700–1000 CE witnessed the consolidation of secular rule in Anglo-Saxon England and an eventually successful defense of the realm against the deprivations of Viking raids and invasions. The many smaller kingdoms of earlier years were gradually absorbed into larger ones until by the late seventh century two kingdoms, Mercia and Wessex, had come to dominate, with Mercia the leading power in the eighth century and Wessex the leading power in the ninth and tenth centuries.

Mercian supremacy resulted from the adroit exploitation of its strategic position in the midlands by two powerful and long-lived kings, Ethelbald (r. 716–757) and Offa (r. 757–796). Under these kings Mercia exacted allegiance and tribute from the smaller kingdoms to the south and east. Offa advanced his power westward against the Welsh, effectively sealing off Wales with an immense earthen embankment known as Offa's Dyke. Offa's able heir Cenwulf (r. 796–821) continued to dominate Kent and East Anglia, although his influence over Wessex and Northumbria waned. King Egbert (r. 802–839) of Wessex's decisive victory over the Mercian Army at Ellendon in 825 was quickly followed by the establishment of Wessex control over Kent, Sussex, and Essex. Within a decade he received the submission of East Anglia, Northumbria, and for a short time Mercia itself. But the hegemony of Wessex in England was concurrent with the decline of Carolingian power on the continent and the coming of the Viking Age.

The Vikings began raiding England in the late eighth century, plundering the monastery of Lindisfarne in 793. Over the next century Vikings raided and eventually invaded England, carving out territory virtually everywhere outside of Wessex and establishing areas of Danish control known as Danelaw. But in 871 the Vikings' ex-

➤ OFFA'S DYKE

An example of the strength and determination of the Anglo-Saxon administrative machinery is Offa's Dyke. Built during the reign of King Offa of Mercia (r. 757–796), it is actually a combination of two dykes. Offa's Dyke is roughly 149 miles long, longer than the famous Roman Hadrian and Antonine Walls combined. The dyke system ran from sea to sea, cutting off the Welsh Peninsula from Mercia. The dyke itself was flanked by a 6-foot-deep ditch that ran along the Welsh side of the fortification. Archaeologists maintain that the rampart was 24 feet above the ditch bottom, providing the Anglo-Saxons with an impressive frontier system against the Welsh.

—Brian Todd Carey

Offa's Dyke passes through the Shropshire countryside. The earthwork formed a boundary, albeit discontinuous, between England and Wales. Built by the Mercian King Offa, it was meant to keep the "savage" Welsh out of England. (Andrew Fogg)

pansion was blunted by an English monarch of considerable talent, Wessex king Alfred the Great (r. 871–899). His decisive defeat of the Danes at Eddington in 878 gave him all of England south of the Thames-Lea line. Alfred reorganized the army, built fortified settlements called *burhs* to protect his subjects, and built a 60-ship navy to challenge the Vikings at sea. During the tenth century Alfred's talented successors would further extend his work of reconquest and political consolidation. Under Edgar the Peaceable (r. 959–975) Alfred's navy was expanded to a force capable of maintaining constant patrols against the Vikings.

After Edgar's reign, England was besieged by a second round of Danish invasions and the accession to the English throne of the Danish king Canute (r. 1016–1035). But after Canute, the last

Anglo-Saxon king, Edward the Confessor (r. 1042–1066) reestablished the Wessex dynasty and consolidated England under his rule just in time for the Norman conquest in 1066.

■ Introduction: Warfare in the Americas and Oceania

Warfare in the Americas and Oceania between 300 and 1000 BCE had many similarities. In most cases, the reason for conflict was control over scarce resources. These resources included food, labor of peas-

ants, and the need to obtain sacrificial victims to offer to the gods. Armies were hampered by the lack of draft animals and wheeled vehicles, ensuring that campaigns were localized and relatively short. Only a few instances exist in which

the warfare included long campaigns and was conducted for territorial gain.

Geographically, Mesoamerica and Oceania had similarities. Although Mesoamerica consisted of a large continuous landmass, the population density was relatively low. Only a few large urban centers existed, and archaeological evidence indicates that they were mostly the residences of rulers and their retainers. Most people lived in agricultural settlements. Likewise, in Oceania the population density was relatively low. Most people lived in small settlements, and the total area covered thousands of miles of ocean with only a relatively few small islands. On larger islands, the population might belong to several different and hostile groups.

The Polynesian societies and the Mesoamerican societies of the period were both stone age civilizations. Warfare was conducted primarily as a socially prestigious affair, with members of the elite engaging in battle to assert their social standing. For the Polynesians, warfare formed an important part of their culture. Hereditary chiefs were expected to participate as a way of confirming that they possessed *mana*, a sort of grace from the gods that followed to them from legendary ancestors. Success in war was a confirmation that one had *mana*. A man who did not succeed in battle was viewed as being out of favor with the gods and might well lose his position. Warfare ranged from raids on neighboring villages to large confrontations. Conflict might well last for generations, until honor was satisfied or one group was exterminated. Mesoamerican cultures, such as the Maya, similarly viewed their rulers as having a supernatural origin. They were the mediators between the people and the gods, and the ruler's success in battle determined that culture's prestige and success. Strong commercial and political standing for a city-state in Mesoamerica could quickly be lost if a ruler was defeated or captured in battle. In both societies, internal enemies might rise up to challenge an elite who was unsuccessful in warfare.

In both societies, military campaigns were short and controlled by the seasons. Both societies lacked animals and wheeled vehicles that could carry supplies for a long campaign. Polynesian warriors were able to use canoes to transport supplies, but this method of supply could work in

only some cases. Supplies were limited to what could be carried on the backs of warriors and porters. Efforts to live off the land were usually not very successful, since local peasants were usually hostile or had little food to share. Campaigns were also not common during the rainy season, since muddy terrain made travel difficult. Warfare also was scheduled around agricultural requirements, since the absence of numbers of men would prevent planting, tending of crops, and harvesting. As a result, campaigns were short and took place relatively close to home.

Warfare was most often waged by members of the elite. Very few city-states in Mesoamerica during this time allowed commoners to participate. The cities of Teotihuacan and Tollan seem to have enlisted most of the men into their armies, but they were the exceptions. The relatively low productivity of agriculture required that most men work in the fields. Also, the responsibility for conducting warfare confirmed the special status of warriors in both societies. Even when Polynesian warriors included all males of a certain age, their leaders and champions were members of the local nobility.

Armaments among both groups were similar. Most weapons were made of wood and stone. Clubs were the earliest type of weapons, supplemented by short thrusting spears and knives. In Mesoamerica, obsidian was often used as a cutting edge for weapons. Pieces were inset in wooden handles to make swords. In Oceania, cutting edges were sometimes organic materials, such as shark teeth. Missile weapons in both cultures included stones thrown with slings. The Mesoamericans added the atlatl, a throwing stick used with spears to add considerable force. Bows and arrows were known to the Mesoamericans but were not often used in combat. In both regions, no group had a technical advantage over their neighbors. The soldiers of some Mesoamerican cities, such as Teotihuacan, were protected with cotton armor and helmets. Shields were also often used in Mesoamerica. Very few Mesoamerican cities, including Teotihuacan and Tollan, used organized formations and tactics. Most Polynesian and Mesoamerican warriors fought individually.

Fortifications were used by both cultures in warfare. Polynesian villages were often protected

by a stockade known as a *pa*. These fortifications could be erected in a very short time and usually served as a haven for people when attacked. Many Mesoamerican cities were similarly fortified, but their walls were more elaborate and included massive stone walls. In both instances, fortifications usually prevented attackers from seizing a settlement. Attackers lacked the logistical support, such as supplies, to mount a lengthy siege. The existence of fortifications was one reason most warfare assumed the character of raids.

Warfare also assumed a ritualistic and religious aspect in Mesoamerica and Oceania. Rulers in both regions appear to have consulted oracles and divination to determine the best days for combat. Certain dates were seen as auspicious, and battles usually avoided religious festivals. Important rulers and warriors in both cultures were distinguished by conspicuous dress, which was often more ceremonial than functional. Precombat rituals and sacrifices were offered. After the battle, prisoners, especially notable captives, were sacrificed to the gods. Trophies, including the skulls of important opponents, were kept by the victors.

Weapons in the Americas

Societies in the Americas between 300 and 1000 CE were stone age societies that normally did not use metals to form their weapons and had only relatively simple technology. Even so, the weapons they used were effective and capable of inflicting great slaughter on opposing warriors. Since no group had a technological advantage over another, victory usually depended on morale

and individual fighting skills. Some city-states, however, were able to establish empires that controlled relatively large regions, thanks to their development of standard formations and tactics.

Archaeological evidence indicates that the oldest weapons used in the Americas were clubs or maces. Simple wooden clubs were replaced by maces with stone heads, which were useful for crushing the bones and muscles of opposing warriors. Further development brought stone axes with sharpened heads. They were able to cleave through rudimentary coverings but suffered from a degree of fragility. Such weapons were effective only in hand-to-hand fighting.

By 300, most fighting men in the Americas used spears of varying lengths. While some spears were used for throwing like javelins, most were retained and used for thrusting at close quarters. Points were made of stone chipped to a sharp edge. Toward the end of the period, obsidian, which could hold an extremely sharp edge, replaced many other types of stones. Obsidian also played a role in the creation of other shock weapons used for slashing attacks. These included wooden swords with obsidian placed around the edges. Knives were also used as a final weapon.

Early defensive weapons included large rectangular shields made of hide. Personal armor, including helmets, began to appear by 300. Shields underwent a corresponding change, becoming smaller and round. Strips of leather or cotton cloth were wrapped tightly around the legs and arms of warriors to help deflect blows. Cotton armor for the rest of the body appeared around 500 in Mesoamerica. This armor consisted of short cotton jackets. They were quilted and filled with material such as rock salt to defeat slashing attacks. Such armor remained in use until the Spanish Conquest. Many Spaniards adopted cotton armor instead of their own, since it was lighter and cooler and provided effective protection from most weapons. Helmets were also worn by important persons. They were usually colorfully decorated with feathers and other ornaments to make their wearer easier to identify. Helmets seem to have been more decorative than practical.

Missile weapons of the era consisted at first of thrown spears. Rocks hurled by slings were also effective against unarmored warriors. These missile weapons were replaced to some degree

by the atlatl, a spear thrower. A warrior would place a wooden stick along his forearm. A groove in the stick held a short spear or dart. When the warrior brought his arm forward, the atlatl would act as an extension and give the extra force. Darts thrown with an atlatl traveled much farther and could penetrate most armor.

Use of the bow and arrow followed that of other missile weapons. Evidence indicates that their use may have spread from Northeast Asia to Alaska. Gradually, bows and arrows diffused to the east and south. Early bows were selfbows, made of single staves of flexible wood. They were not very powerful but were useful especially for hunting. The power of the bows was increased by attaching sinew, horn, or bone to the wooden staves followed by compound recurved bows. The more powerful bows were most common in northern North America, and little evidence of their use in Mesoamerica exists.

Bows and arrows were widely used in the American Southwest and were familiar to the Mesoamericans but were rarely used in warfare. Most noble warriors preferred the atlatl, which required extensive practice to be accurate. Because arrows were most effective when used in massed volleys, the bow and arrow was most likely used by lesser-trained commoners. The ability of commoners to pose a serious threat to noble warriors' monopoly on warfare may have been a factor in undermining the existing social structure in Mesoamerica. Parallels may be drawn to the advent of gunpowder weapons equalizing peasants and knights in early modern Europe.

Teotihuacan, which dominated the first part of the era, apparently had trained warriors using uniform weapons and standardized tactics. These included specialists armed with atlatls who delivered missile fire on their opponents. This was followed up by warriors armed with thrusting spears. Later city-states, such as Tollan, armed their warriors with atlatls and swords, allowing them to use missile fire followed by shock attacks.

Warfare among Mayan Cities

During the Classic Period (200–900 CE), Southeastern Mexico, Guatemala, Belize, and part of Honduras were the home of Mayan cities. They were organized in a number of independent city-states that controlled varying amounts of territory. Warfare was a nearly constant part of their existence, especially between 400 and 900. It included commercial and political elements but also had important religious aspects.

Before 300, most Mayan conflicts were indecisive. Rulers raided each other's territory and engaged in bloody pitched battles, but imperial expansion was rare. All sides fought with basic stone age technology, such as thrusting spears with stone points. Each city had an organized militia that consisted of virtually all adult men. Their leaders were members of the nobility, with the ruler and his family serving as ultimate leaders. The size of Mayan armies is unclear. For important campaigns, thousands might have been mobilized. For the more common raids and smaller expeditions, only a few hundred men might have been included. One of the most important reasons for limited numbers was the logistical problems supporting many soldiers. Without draft animals or wheeled vehicles, all supplies had to be carried on men's backs or confiscated from local peasants. When supplies ran out, the armies returned home. Another reason for limited numbers was the need for agricultural laborers. Campaigns were timed for periods when workers were not needed for planting or harvesting.

One reason for war between the Maya cities was to gain control of populations and arable land. Wealth was primarily based upon agricultural products, such as cacao beans or cotton.

More territory also meant that more food could be produced to support increasing populations. Victory in war often resulted in the control of frontier territories and their workers. Another reason for conflict was commercial. An important trade between the Maya cities and other groups was important. Control of trade routes and the establishment of trading colonies allowed cities to import products like obsidian, decorated pottery, and metal objects more easily while exporting agricultural products.

Archaeologists have recently become more convinced that religion played an important role in decisions to go to war. Mayan artworks indicated that the capture of important persons for sacrifice to the gods was paramount. Seizure of an opposing ruler usually ended a battle immediately. A multitude of gods were worshipped by all Mayans. The most important for warfare was one known as 18-Rabbit Serpent. Mayans believed that the gods accompanied them and fought with them. The Maya regarded their kings as descendants of gods and displayed them as such in their art. Brightly colored banners and other devices on long poles were used in battle to represent gods and to help give directions to warriors. Kings and other nobles wore colorful costumes in battle, representative of various gods. Sacred litters with representations of the gods usually accompanied armies on campaigns and were special prizes to be captured. Because the gods and their favors were always present for the Maya in everything in life, success in war defined a king's power as a representative of the gods. Failure, especially capture and sacrifice by another ruler, indicated that a ruler had lost the gods' favor.

Although most wars between Maya cities consisted of short, often bloody actions, major battles were not unknown. These battles may have included thousands of warriors on each side. Although the archaeological evidence is unclear, rulers may have made arrangements in advance. Priests would have let the kings know what dates were acceptable to the gods and consulted auguries to check for auspicious signs. Formal tactics in the battles were rare, and most fighting seems to have been done by individual nobility. Although the capture of live enemies

for sacrifice to the gods was one goal, Mayan battles could be extremely bloody.

Although warfare was endemic among the Maya, conquest of another state was only possible when that population could be incorporated into the victor's population. One of the earliest examples is Tikal's conquest of the neighboring city of Waxaktun in 378. The two cities had fought before, but Tikal's victory in this year was decisive. Tikal's king installed his brother on the throne after eliminating the old ruling family of Waxaktun. One reason the people of Waxaktun seemed to accept absorption into Tikal was that credit for the victory was given to 18-Rabbit Snake, a foreign war god imported from Teotihuacan. The Tikal victory proved that 18-Rabbit Snake was a more powerful god, giving the new king from Tikal credibility.

Victories were celebrated with sacrifices of captured enemies but also by destroying the defeated city's religious power and symbolism. Stone stela were raised by the victors with information about their victory. In the capitals and ceremonial centers of the losers, religious buildings were ritually desecrated to destroy their powers. Masks of the gods were disfigured, and bonfires were built in sacred chambers. Pottery used in rituals was smashed, and white marl was spread over the floors and doorways. The destruction symbolized the victory over the loser's gods.

Warfare was common for most of the classical era of the Maya. No city-state was able to establish a lasting dominance over the others. By 900, Mayan society in the Yucatan collapsed, apparently from internal pressures caused by warfare and ecological disaster.

The Polynesian Way of War

Warfare was an important part of Polynesian society. Most social disputes were solved with violence, whether they were between different groups of people or within the same political group. Because of the limited resources available on most Polynesian islands, warfare could be caused by increasing populations and the competition for those resources. It could also be caused by social ambitions and the need among elite groups to prove that they deserved their positions.

Around the beginning of the Common Era, Polynesian groups began a long-distance colonization of the islands of the central Pacific. This amazing process was apparently spurred by increasing populations and the need to escape violent conditions in their homelands. The process was repeated throughout the era as populations became settled, grew, and then came into conflict over control of the new islands. Although ancient Polynesians left no written records, their oral traditions and archaeological evidence indicate that the first settlements were made on islands in areas with abundant water resources. As the populations expanded, groups formed new communities in more marginal areas of the island. Eventually these communities expanded until their borders came into conflict with each other. If populations continued to increase, the groups would engage in war with each other until they were conquered or forced to flee the island. Warfare was brutal and usually without mercy. Conflict between groups sometimes lasted for generations. Captives were used as human sacrifices in religious rituals. On some islands, cannibalism may have taken place as a part of these sacrifices.

Conflict was also the result of social stratification and stress. Polynesian populations were

divided into an elite class of chiefs and the mass of commoners. Status was determined by birth. Chiefs were believed to possess *mana*, a force given by the gods through the ancestors of the elite class. Mana was made manifest through the prowess and power of the chiefs. A man who was not successful in war was believed to be without mana and lost his position in the society. On the other hand, successful warriors from the common class could rise in social status. Some apparently demanded and received the benefits of chieftdom because of their success in combat.

Because of endemic warfare in Polynesian society, fortifications were common. Most villages or settlements had wooden walls and were sited on easily defended terrain, such as hill or ridge tops. Known as *pa*, they also included large storage pits for food to allow the population to withstand a siege if necessary.

Spears were common weapons in Polynesian warfare. They ranged from 6 to 15 feet in length. Natives amazed later European explorers with their ability to grab thrown spears in mid-flight and use them to fend off other spears. Slings, strangling cords, and tripping devices were also common. War clubs from ironwood or other dense wood were used in close combat and were often elaborately decorated.

■ Introduction: Fighting Forces—A Global Overview

Globally, the period 300–1000 CE witnessed both change and continuity in warfare largely due to increased reliance

on cavalry, advances in technology, and often—except in sub-Saharan Africa and the Americas—increased reliance on navies.

In Eurasia, migrations and invasions of steppe peoples into civilization zones precipitated the decline and fall of great civilizations in China, India, and Europe, changing the way these civilizations made war and raising the value of cavalry during this period. In China, the infantry-based armies of the late Han dynasty began to include more cavalry in their tactical mix to meet the persisting threat of horse nomads on their northern frontier. Han commanders even went so far as to hire nomadic horsemen as mercenaries because of their skill as mounted archers using powerful composite bows. After the fall of the Han dynasty in 220, Chinese armies were heavily influenced militarily by the influx of central Asian peoples who brought with them saddle and stirrup-stabilized cavalry, both of these inventions coming from horse nomads. But policing the vast territories of China required large multiethnic infantry contingents, so footmen remained an integral part of the Chinese military system throughout the later Sui (581–618) and Tang (618–907) dynasties.

Indian military structures were also impacted by the influx of steppe peoples into the subcontinent in the period 300–1000. During the Kushan Kingdom (ca. 150 BCE–ca. 200 CE) Indian warfare was influenced by central Asian martial practices, dispensing with the war chariot so popular in earlier periods and emphasizing cavalry tactics over large infantry engagements. The rise of the indigenous Gupta dynasty (320–ca. 550) returned India to more traditional ways of warfare, stressing combined-arm cooperation using heavier cavalry, infantry, and war elephants. The Gupta infantry could stand against the cavalry from the central Asian steppe because they used the bamboo and steel longbow that could shoot armor-penetrating missiles. The Gupta dynasty was nearly destroyed by another steppe people, the Huns, whose cavalry armies swept into India from the northwest in the late fifth and sixth centuries, but an alliance of Hindu armies drove the Huns out of India in 528. The conquest and occupation of the Sind by Arab Islamic armies in the early eighth century introduced Islamic martial practices to Indian war making, while the northwestern frontier of India was threatened again in the tenth century with the coming of Turkic Ghaznavids (963–1187),

who utilized steppe warfare showcasing lighter horses and mounted archery. Turkic martial organization and tactics would continue to influence Indian warfare through the numerous dynasties that made up the later sultanates of Delhi (1206–1527).

Persian warfare under the Sassanids (224–651) mirrored that of their chief adversary, the Byzantines, with sophisticated armies using well-armored heavy cavalry cataphracts with infantry support being the norm, although the Persians were also famous for their elephant corps. The rapid rise and expansion of Islam destroyed the Sassanids and quickly put the Byzantines on the defensive. Early Arab Muslim armies were not adept at siege warfare like their Chinese, Indian, and Byzantine counterparts, preferring to use their camel corps to cross deserts, bypass fortifications, and raid the countryside. But later Islamic armies adopted the technologies and tactics of their conquered peoples, transforming Muslim armies with heavier Persian-styled heavier cavalry and better siege trains, while in North Africa, Berber martial practices mixed with Arab practices as Islamic armies crossed into Europe and conquered the Iberian Peninsula after 711. The conversion to Islam of the Ghazni and Seljuk Turks brought light cavalry archers into Muslim warfare often with spectacular effect, as the Seljuk defeat of Byzantine forces at Manzikert in 1071 illustrated.

In Europe, the Roman Army was in decline beginning in the fourth century and was unable to defeat Germanic tribes penetrating the Roman frontiers in raiding expeditions, a process that accelerated in the fifth century. Drill and discipline suffered as Germanic troops were allowed to join the Roman military, often with their own commanders, and by the fall of the western Roman empire in 476, the Roman Army was indistinguishable from its barbarian enemies. Cavalry, rather than infantry, was the featured military arm of emerging Germanic kingdoms, especially after the diffusion and widespread use of built-up saddles and stirrups created more efficient lancers in the ninth century. This West European heavy cavalry provided Catholic Europe with the strategic mobility to meet the threat of the Magyar and Viking menace, and by the beginning of the

eleventh century heavy cavalry was the dominant military arm in western Europe.

Martial practices in North Africa in the period 300–1000 were heavily influenced by Roman, Vandal, Byzantine, and later Islamic warfare, while in sub-Saharan Africa tribal warfare was the norm. Between 700 and 1000 the kingdom of Ghana emerged as the dominant political and military force in sub-Saharan Africa and was the first of the western Sudanese empires to establish a large professional army. During this period, cavalry was not a featured military arm as it would be in the later kingdoms of Mali and Songhai. Instead, infantry armed with short-handled wood, stone, and iron-tipped thrusting spears, javelins, and iron swords and protected by bamboo shields was the main fighting force. These light troops were ideally suited for fighting in the varied topography of the Sahel, savannas, and jungles that surrounded this West African kingdom. War revolved around protecting the gold, ivory, and salt trade; iron mining; and the seizure of captives for the growing slave trade with the Mediterranean world. The expansion of Islam into West Africa after 1000 changed military structures, highlighting the role of professional soldiers and creating large standing armies as well as highly disciplined cavalry forces.

In the New World, patterns of warfare in the period 300–1000 continued to be centered around tribal conflicts using small armies with stone age martial technologies like atlatls, bows, spears, and clubs for control over people, trade routes, and limited natural resources like fresh water, arable land, and access to obsidian and chert, strategically important materials for constructing tools and weapons for societies that did not use copper, bronze, or iron. Where states did exist, warfare was highly ritualized, and there is still debate among scholars on the role of human sacrifice as a motivation for raiding and conquest. One of these states, the Teotihuacan civilization in the Valley of Mexico, was capable of fielding an army of nearly 20,000 men when augmented by allied communities. This army utilized battle standards (a first for pre-Columbian armies), and there is indication that soldiers were equally adept in shock combat using thrusting spears and clubs as they were using standoff missile weapons like javelins and atlatls (bows were not used).

For protection, quilted helmets and shields were utilized. Farther east the classical Maya (ca. 250–ca. 900) organized their society in city-states like ancient Greece and continuously fought civil wars for control over the region's resources. Archaeology reveals that the Maya built fortifications around their urban centers, but modern scholars are still deciphering sources to understand Maya tactics and military organization. Most martial activity seemed to be done by a military caste that most probably fought in open formations and used missile weapons like bows, atlatls, and spears and then closed for hand-to-hand combat with thrusting spears and clubs. Textual and archaeological evidence supports increased Maya warfare at the end of the millennium, perhaps due to increased competition for dwindling resources. Less is known about the military capabilities of the central Andean civilization of the Moche (ca. 100–ca. 800). The Moche were organized like the Maya in loosely connected communities, and limited archaeological evidence suggests that Moche warriors fought without armor and with atlatls and clubs, while defensive works at the end of the civilization point toward internal social unrest, possibly because of climate change.

At sea, Old World navies from East Asia to Europe continued to use wooden ships powered by oar and sail. In China, the Han dynasty's so-called Tower Ship Navy was improved upon by later Tang and Song rulers, and the Chinese proved masters of seaborne and riverine operations. Farther west the Gupta empire maintained a navy and was able to control regional waters around the subcontinent, while the Sassanids in Persia used their navy to attack across the Persian Gulf to Arabia before the advent of Islam. In the Mediterranean, Byzantine and Arab Muslim warships were usually smaller derivatives of earlier Roman galleys and carried contingents of marines for ship-to-ship fighting and amphibious operations. The incendiary known as Greek fire was used to good effect by the Byzantines to destroy a large Muslim fleet in 678 and was soon in the arsenal of most civilizations in the region. Farther north, Scandinavian shipwrights constructed large clinker-built longships capable of extraordinary transoceanic journeys and deep river penetrations, becoming the Vikings' favor-

ite tool for raiding and invading Europe from Ireland to the Ukraine and colonizing Iceland, Greenland, and, for a short period by 1000, parts of the northeastern coast of North America. There is no evidence to support the existence of large organized navies in sub-Saharan Africa and the Americas in this period.

The Byzantine Army

During the period 300–1000 CE the Byzantine empire faced numerous challenges from Persian encroachment, Germanic invasions, and Islamic expansion, yet Byzantium was almost always ready to fight. The long Byzantine survival was due in part to the remarkable performance of a balanced combined-arms army. The composition of the Byzantine Army differed from that of its Roman predecessor in that cavalry, rather than infantry, took a dominant position. This switch in emphasis probably arose due to prolonged martial contacts with the Near East. The most formidable threat to the eastern part of the Byzantine empire came from the successors of the Parthians, the Sassanid Persians, who fought like their forerunners almost exclusively with light and heavy cavalry. Due to close martial contacts, some Byzantine heavy cavalry, called *clibanarii* or *cataphractii*, carried bows. The cataphract functioned as a heavily armored lancer or as a mounted archer. With the adoption of the stirrup sometime from the late sixth to the late seventh century CE, the cataphract became for the first time a true lancer because he could now use the synergy of the horse and rider and aim through his target instead of jabbing down or loosening his spear with every pass, as classical heavy cavalry had done for centuries.

Second to cavalry in importance in Byzantine warfare was light infantry. Byzantine light infantry wore very little body armor and carried a composite bow with a quiver of 40 arrows, a small shield, and an axe for close combat. Infantry not skilled with the bow carried javelins. Warfare against mounted archers in the east illustrated the effectiveness of these foot bowmen over enemy horse archers because light infantry fired bows with a greater range from a more sta-

THE BYZANTINE NAVY, 300–1000 CE

Naval power was inextricably tied to the fortunes of the Byzantine empire in the period 300–1000. Under emperors Constantine (r. 324–337) and Justinian (r. 527–565), the Byzantine fleet was modern and large and could project power to the far corners of the Mediterranean Sea, maintaining the flow of goods and the prosperity of the empire. The standard Byzantine warship was the *dromon*, a galley with two banks of oars and an average crew of 200 oarsmen and 70 marines. Swifter and lighter warships called the *pamphylos* and the *ousiakos* were also used, and special transport ships were used for carrying horses (*onerarai*) and for projecting Greek fire (*siphonophores*). Byzantium faced a new naval threat with the emergence of Islam in the seventh and eighth centuries. Muslims seized important naval bases along the Mediterranean littoral and islands and placed the Byzantine capital under siege twice (674–678 and 717–718). In the ninth century, Byzantine emperors Michael III (r. 842–867) and Basil I (r. 867–886) revived the eastern Roman Navy. But this revival was short-lived, as future emperors increasingly employed mercenary Venetian fleets to police their waters. When a Russo-Swedish navy attacked Constantinople in 1042, the Byzantines pressed into service aging hulks and refitted transports to defend the city, and in 1204 there was no Byzantine navy present to meet the Catholic crusaders during the Fourth Crusade (1202–1204).

—Brian Todd Carey

ble platform, the ground. Byzantine light infantry were supported in the field by heavy infantry modeled after classical Roman infantry. Byzantine heavy infantry wore mail or lamellar armor and helmets and carried a large round shield. Equipped with a long spear and sword, Byzantine heavy infantry normally massed in phalanxes (compact bodies of troops) 4, 8, or 16 ranks deep on the battlefield. This infantry generally formed up as a second line behind the cavalry, relying on the cataphracts to break up the enemy formation before following up, or in the center with cavalry on the wings.

Using this military organization, Emperor Justinian (r. 527–565) was able to reconquer most of the Mediterranean basin. After his death

Miniature from the Scyltizes Chronicles (eleventh century CE) depicts a battle waged in 842 CE between Byzantine and Arab cavalries. (Werner Forman/Art Resource, NY)

in 565, the Byzantine (eastern Roman) empire faced crisis after crisis. Constantly besieged by the Slavs and Bulgars in southern Europe, by Persians in Mesopotamia, and, from the mid-seventh century onward, Islam from Africa and the Levant, the Byzantine empire found its military and fiscal resources relentlessly stretched. Still, despite being deprived of all its African and Asian possessions except Asia Minor, the Byzantine empire maintained itself for centuries as a formidable eastern Mediterranean power.

Unable to sustain a professional standing army, Emperor Constans II (r. 641–668) settled his mobile armies in specific districts called *themes*. The new organization of themes introduced regionalized army groups under the command of a senior general, or *strategoi*. The themes acted as both regional frontier troops and as mobile field armies. Outside of military organization, the themes were also an important part of imperial social structure. The soldiers of a particular theme were the legal holders of the land itself, a development that came in the form of imperial land grants within the particular region and were similar to the land grants during the early Roman empire.

Beginning in the mid-seventh century, soldiers of the themes supported themselves from land grants within their districts because the state's only remaining means of supporting its soldiers seems to have been giving them land, most probably from imperial estates. For the most part, the themes acted as a defensive force,

but later emperors would take an interest in regaining lost territory. Emperor Constantine V (r. 741–775) created several elite cavalry units called *tagmata*, first as a reaction to a rebellious theme in northwestern Anatolia and then for offensive campaigns against the Arabs and Bulgars.

The basic administrative and tactical unit of the Byzantine Army from the seventh century was the *banda*, consisting of about 400 soldiers commanded by a tribune and, later, by a count. The *banda* were about equally divided into infantry and cavalry, with the dominant weapon system being heavy cavalry (historians believe that cavalry made up 20 percent to 40 percent of a Byzantine army, depending on where it was created and where it was operating). Infantry archers and javelineers usually accompanied the heavy infantry, acting as skirmishers. Five to eight *bandum* (2,000–3,200 cavalry and infantry) formed a *turma*, two or three *turmae* (4,000–9,600 soldiers) constituted a *thema*, and three or four *themae* together became a Byzantine field army, usually numbering 25,000 to 30,000 men. The entire Byzantine Army was not very large, probably never exceeding 150,000 men total. For all practical purposes, the *thema* replaced the legion as the premier strategic unit of maneuver in Byzantine warfare.

The Byzantine Army differed from its Roman predecessor in one significant way: the level of professionalism in its military. Although the soldiers of the *thema* became increasingly a defensive militia force, the core of the Byzantine Army consisted of professional soldiers organized in homogenized cavalry or infantry units called *tagmata*, equal to the size of the *thema*. These soldiers were the best-trained troops in the empire, serving as Constantinople's garrison and as the chief expeditionary force for the emperor. When the emperor went on campaign, the *tagmata* and local *themae* combined to create a field army.

For the next 300 years, Byzantine field armies enforced a conservative, careful strategy of limited military aims, seizing land in the Balkans from the Bulgars and territories in Anatolia, Syria, and Armenia from the Muslims. But by the coming of the millennium, the overall professionalism of the Byzantine Army dropped precipitously, forcing emperors to rely increasingly on foreign mercenaries, especially Russo-Swedish soldiers

called the Varangian Guard, instituted by Emperor Basil II (r. 976–1025) in 988 CE. By the beginning of the eleventh century, emperors added Normans, Germans, and Turks to their payrolls, serving under their own officers in units with their own organization. As the themes declined in combat efficiency, these mercenaries began to replace the Byzantine Army rather than merely complement it. But despite these changes, the Byzantine empire would not be able to meet the growing threat of the Seljuk Turks, who defeated the eastern Romans decisively at Manzikert in 1071 and overran most of Anatolia, forcing Byzantium to ask for assistance from the papacy and precipitating the crusades.

Merovingian and Carolingian Armies

Early medieval western Europe was dominated by the Franks, a fierce Germanic people who settled into what is today the Netherlands, Belgium, and northern France. Split into two major dynasties, the Merovingian (ca. 450–751) and the Carolingian (751–987), the Franks possessed a solid military and very able commanders. The first important king of the Merovingian dynasty, Clovis (r. 480–511), converted to Catholicism in 496 CE, and his subsequent alliance with the papacy brought the Catholic Church's organizational capabilities to the Germanic kingdom. Sanctioned by the pope and allied with Catholic missionaries, Frankish kings and nobles spread Catholicism and civilization east of the Rhine and ushered in three centuries of Frankish cultural, political, and military supremacy in West European affairs.

The core of Clovis's army consisted of a personal bodyguard of professional warriors (*socii* or *exercitus*) bound to service by oaths of loyalty

➤ CAROLINGIAN FORTIFIED BRIDGES

In order to block or discourage seaborne penetrations of the Viking Great Army into the heart of western Europe, the Frankish king Charles the Bald (r. 843–877) built fortified bridges across strategic waterways. Viking marauders preferred soft targets such as churches, monasteries, and unwall towns and cities and raided these sites from the safety of their longships. To obstruct these upriver raids, Charles placed these fortified spans at strategic locations such as Charenton-le-Pont on the Marne River, Auvers on the Oise River, and Paris, Pistres, Pontoise, and Trilbardou on the Seine River and built and garrisoned the bridges with men too poor to go on campaign. The bridges consisted of a wooden superstructure and bridge-head forts of wood and stone. The effectiveness of these fortified bridges is mixed. With the exception of Paris, most of these bridges had limited success because of the difficulty of maintaining garrisons. Most were attacked and destroyed while under construction. Charles also ordered the restoration of walls at Orleans, Le Mans, and Tours and construction of a wall around the important monastery of St. Denis near Paris. After Charles's death in 877, control of the fortified bridge near Paris fell to local commanders, who despite their best efforts were unable to hold back a second Viking Great Army in 885 that sailed up the Seine and attacked Paris.

—Brian Todd Carey

and commanded by officers of the court (mayor of the palace, counts of the palace, and marshal). If a larger army was required, Clovis and his successors would pull together an *exercitus generalis*, or general army, made up of magnates and their followers. In the second half of the sixth century a general levy (*heerbann*) of able-bodied men appeared, led by the local count (*comes*). Duties included maintenance and garrisoning of fortifications, roads, and bridges and serving on campaign. The period of service was probably a maximum of six months and was limited by planting and harvesting. The *heerbann* usually served as infantry in battle wearing little or no defensive protection, usually just a helmet; carrying a shield; and employing a light lance, a long sword, or a long single-edged dagger known as a

scramasax. Infantry also carried the *angon*, or barbed-headed javelin, as a missile weapon. Archers were never present in large numbers in Frankish armies except during the reign of Charlemagne. The wealthier noble horsemen wore mail hauberks and helmets, carried round convex shields, and used their long swords as frequently as their lances for attack. These less-armored heavy cavalry often employed javelins or throwing axes known as *franciscas*, creating a fusion of heavy and light cavalry.

Eventually, a succession of weak Frankish kings under the Merovingian dynasty led to the practice of actual power being wielded by the mayor of the palace. Through this office the next Frankish dynasty, the Carolingian, rose to power. The most significant of these Carolingian mayors, Charles Martel (ca. 688–741), earned his military reputation as an ardent campaigner, consolidating the power of his office and expanding centralized control over Austrasia and Neustria in what is now roughly northern France and northwestern Germany. But Charles Martel faced new challenges to his rule with the expansion of Islam into the Iberian Peninsula. Muslim armies crossed into Europe in 711 and conquered the Visigothic kingdom in Spain by 718, using northern Spain and eventually southwestern France as bases of operations for raiding expeditions into Christian Europe. Charles Martel blunted the most famous of these raids at the Battle of Tours in 732. Charles Martel's army was primarily a force of mounted infantry who dismounted to fight. Once dismounted, these troops fought in the same dense shield walls as their Frankish ancestors had centuries earlier, with men from the same estate or towns standing together and with feudal vassals gathered around their lords. There is some evidence that stirrup-stabilized cavalry entered the Frankish art of war after the Battle of Tours.

Charles Martel's grandson, Charlemagne (r. 768–814), would build upon his inheritance and create the most powerful kingdom in western Europe since the Roman empire. To defend against foreign invasions, Charlemagne established border provinces known as marches (*marcae*) consisting of a network of fortresses joined by roads to protect the hinterland and to be used as bases for offensive campaigns. An ap-

pointed military governor, or *markgraf*, commanded each of these marches, granting newly conquered territory to nobles and veterans in exchange for military service.

Under Charlemagne the majority of the Frankish Army was still serving as infantry, although there was a steady increase in the use of cavalry in the Carolingian period. This emphasis on mobility was due to constant campaigning on the borders against fast-moving raiders (Avars, Muslims, Vikings, and Magyars). Because of the expense of the knight's panoply and the time and practice required to become a skilled equestrian and lancer, the medieval heavy cavalryman needed to be economically supported. Consequently, lords who wanted the services of this new and expensive weapon were required to grant each vassal a benefice, a piece of land from their hereditary possessions that provided the vassal's economic support. In return for this grant of land the vassal provided the lord with military service. By the ninth century, the benefice became a fief as it acquired new characteristics involving the exercise of political power. The fief differed from the benefice in that the vassal enjoyed the rights of jurisdiction or political and legal authority within his fief.

Stirrup-stabilized heavy cavalry also made its appearance in this period. The stirrup, which was believed to have originated in central Asia in the second century BCE, was probably introduced to the West sometime before the eighth century either by the Byzantines, the Muslims, or the Avars. When combined with a saddle built up at the pommel and cantle for longitudinal support, the stirrup welded rider and horse together. Rather than thrusting out himself, the lancer now held his weapon at rest in the crook of his arm, using the combined weight of his body and his charging mount to deliver a blow of unprecedented violence. Utilizing the energy of the horse and the newfound stability provided by the stirrup, this new heavy cavalry used its spears as lances to defeat its enemies and secure a position at the top of the social hierarchy. The Franks became famous for the irresistible charge of their heavy cavalry, and their tactics spread from France to all of western Europe by 1000 CE.

Carolingian dominance in western Europe waned after the death of Charlemagne in 814. A

second age of invasions swept across the continent as Muslim, Magyar, and Viking marauders severely eroded Frankish defenses. What remained of Charlemagne's empire was split into three parts with the Treaty of Verdun in 843, although the invaders pummeled these smaller kingdoms as well. Later Carolingian kings used fortified bridges to impede upriver Viking assaults, while another strategy was to give land grants to Viking chieftains under the condition that these rulers would protect the realm from their brethren. The most famous and historically consequential of these land grants took place in 911 when King Charles the Simple (r. 893–923) granted the lands at the mouth of the Seine River to a band of Vikings under Rolf the Walker (later known as Rollo), creating the duchy of Normandy. Although the Carolingian dynasty ended in 987, the martial lineage of Clovis, Charles Martel, and Charlemagne shifted to the Normans, inheritors of both Viking and Frankish martial institutions.

Chinese Armies, 300–907 CE

In the period between 300 and 907 CE the Chinese Army witnessed great change as the Middle Kingdom succumbed to foreign invasion, reshaping its military institutions. After the Han dynasty fell in 220 CE, China was divided into three Chinese states, the Wei, Wu, and Shu Han, though these states did not last long. In 266, the Jin dynasty attempted to unify China again, though it ultimately fell in 316 when northern barbarian tribes divided northern China among themselves, setting up kingdoms that were Chinese in name only. Ethnic Chinese rule continued in the south, but the influence of these northern nomads on Chinese warfare was both

revolutionary and long-lasting, impacting the Chinese art of war under the later Sui (589–618) and Tang (618–907) dynasties.

The armies that founded the Han dynasty in 202 BCE consisted mainly of infantry, supported by contingents of cavalry and chariots. Foot soldiers wore caps or iron helmets and were protected by leather or iron lamellar armor and fought with swords, spears, or halberds. Although archers were present, crossbowmen figured prominently in the Chinese art of war. But persistent contacts with central Asia from the mid-second century BCE onward forced the Chinese to adopt exclusively cavalry forces to meet the barbarian threat. Han cavalry utilized swords, spears, halberds, and both bows and small crossbows and would dismount in battle if necessary. Han commanders hired nomadic horsemen as mercenaries, valuing their archery skills from horseback.

➤ TURNING POINT IN CENTRAL ASIA— THE BATTLE OF TALAS RIVER

The Battle of Talas River in 751 was a major clash between two powerful empires for control over central Asia. Under the Tang dynasty (618–907) Chinese armies pushed farther west, recovering lands lost since the fall of the Han dynasty, but encountered resistance from both Tibetans and the growing influence of Muslim Arabs in the Tarim Basin. In 747, a Tang army of 10,000 mounted Chinese soldiers and non-Chinese allies pressed as far west as the Pamir Mountains, commanded by the Korean general Kao Hsien-chih. Chinese troops defeated a Tibetan army and stabilized the Tibetan frontier but four years later faced a new Arab dynasty, the Abbasid (750–1258), at the Battle of Talas River (near modern Taraz in Kyrgyzstan).

General Kao commanded an impressive host of 30,000 soldiers (20,000 Chinese and 10,000 Qarluq mercenaries). There are no records as to how many Muslim soldiers were present. The fierce battle lasted five days and only came to a decisive conclusion when the Qarluq mercenaries defected to the Arab side. The Tang army was routed in the only major military confrontation between Muslims and the Chinese armies in this period. Tang westward progress was halted, and Islamic influence permeated central Asia. Captured Chinese artisans gave the West paper manufacturing, which was taken back to Samarkand and Baghdad and then spread to Damascus, Cairo, and Morocco before reaching Europe by way of Spain and Italy. Islam's control of the Silk Roads initiated a golden age for the Abbasid caliphate, while the loss at Talas River severely weakened the Tang emperor and precipitated the An Lushan Rebellion (755–763), leading to the decline of the Tang dynasty.

—Brian Todd Carey

Chinese military history changed dramatically in the fourth century CE with the introduction of stirrup-stabilized heavy cavalry cataphracts, well-armored lancers riding larger horses. Stirrupless heavy cavalry was a common feature in West Asian warfare going back to the sixth-century BCE Achaemenid Persians, with this form of warfare slowly making its way east across central Asia over the centuries. The Xiongnu in northwestern China first obtained cata-

phract panoplies in 312 from captured Xianbei warriors who migrated south from Manchuria, introducing the cataphract into China proper by midcentury. With the addition of the stirrup and a saddle with built-up pommel and cantle, the Chinese cataphract became a true lancer, using the synergy of the horse and rider and aiming through his target instead of jabbing down or loosening his spear with every pass. Due to the expense of fielding heavy cavalry cataphracts, poorer tribesmen continued to be employed in large numbers as light cavalry archers.

Barbarian commanders controlling Chinese territory soon recognized the importance of conscripting native Chinese infantry to garrison cities and control the countryside. Under the Northern Wei dynasty (386–534) early forms of the *juntian* (“equal field”) and *fubing* (“soldier-farmer”) military systems were created. The *juntian* system assigned 140 *mou* (about 19 acres) of agricultural lands to a peasant family to work, both slowing the accumulation of land by wealthy families and providing the economic support for the soldier-farmer. Under the *fubing* system, each regional military headquarters (*fu*) commanded about 1,000 soldier-farmers who could rapidly mobilize for war. During peacetime, these men worked their allotted land and served one-month annual tours garrisoning the capital. Most *fubing* militia units were located in the northwest and were best suited for the annual campaigning cycle of an expanding empire.

China was unified again in 589 under the Sui emperors Wendi (r. 581–604) and his son Yangdi (r. 604–618), who came from a northwestern aristocratic family of mixed Chinese and barbarian ancestry. Sui military institutions continued to reflect nomadic influences. Forty percent of the Sui dynasty's 60 highest-ranking officers were non-Chinese, while 87 percent had served under the previous Xianbei dynasty. The Sui's vigorous foreign policy required the organization and deployment of considerable military force. Military expeditions were sent west, driving out the nomadic peoples of Gansu and eastern Turkestan. Wendi's policy exploited the internal divisions among these Steppe peoples, supporting rival Turkish factions against one another. Colonies were established along the western Silk Roads, while to the south Sui

armies marched into Champa in central Vietnam and crossed the Strait of Formosa to Taiwan. Three unsuccessful campaigns against the northern Korean state of Koguryo strained the dynasty's manpower and material resources, precipitating rebellion and the assassination of Yangdi in 618. Yangdi was replaced by the Sui dynasty's top general, known posthumously as Gaozu (r. 618–626), who founded the Tang dynasty. Gaozu's second son enjoyed considerable success as a military commander before killing his brothers and forcing his father to abdicate, becoming Emperor Taizong (r. 626–649). He pushed Chinese hegemony west across the Tarim Basin to the Pamir Mountains in modern Tajikistan but, like the Sui before him, failed against Koguryo in Korea.

Both the Sui and early Tang utilized the fubing military system, though with different command structures. The Sui allowed local administrators to control these units, while the Tang placed all of the soldier-farmers under the Ministry of the Army (*ping-pu*), giving the emperor centralized control. The Tang maintained some 600 fubing units, each containing between 800 and 1,200 men. These soldier-farmers were liable for military service between the ages of 21 and 60. Units contained both infantry and cavalry and were subdivided into *tuan* of 200 men, *tui* of 50 men, and *buo* of 10 men. Officers were permanently employed, while the soldier-farmers reported to the capital at Chang'an (modern Xian) on a rotating basis depending on how far away they lived. Soldiers who lived up to 500 *li* (about 160 miles) from the capital served 1 month in every 5, while those who lived 2,000 *li* (about 640 miles) away served 2 months out of every 18. Early Tang officials also used a similar system to man the far reaches of the empire, rotating men every 3 years in frontier garrisons.

The fubing system worked well at first because most of the soldier-farmers were already located in the northwest and close to the capital. Militia performed well as peacetime garrisons or in short-duration campaigns but proved inadequate for staffing static fortifications in frontier regions or in prolonged campaigns like those fought in Korea. If soldiers were kept on campaign too long, their agricultural fields suffered at home, weakening both the family and the

state. By the reign of the Tang emperor Xuanzong (r. 712–756) the fubing system had declined as well-off families began to pay substitutes or evade military service altogether. Xuanzong replaced the militia system with a standing army that, by the 740s, reached a strength of half a million men and 80,000 horses. The ethnic makeup of this new standing army reflected the success of Tang imperium and included Han Chinese, Koreans, Kitan, Turks, and Sogdians, preserving the Chinese-Inner Asian mixture characteristic of Sui and early Tang armies. Central Asian tactics and equipment continued to shape Chinese armies, with many ethnic Chinese horsemen favoring the traditional Turkish combination of light lance and bow over the more cumbersome cataphract panoply. Tang generals favored cavalry for its strategic mobility, with some Tang expeditionary forces in central Asia consisting entirely of ethnic Chinese or allied horsemen. When infantry was included, it was often mounted in order to keep up with the cavalry.

In 747, Emperor Xuanzong sent his mobile army west across the Pamirs to prevent the Muslim Arabs and Tibetans from joining forces. This strategy initially worked, but four years later the Tang Army suffered a devastating defeat against the new Abbasid caliph at the Battle of Talas River near Samarkand, ending Tang ambitions in this area and opening central Asia to Islamic influence. An alliance between Tibet and Nan Zhou in southwestern China further exacerbated the Tang's strategic position. To meet these growing threats on the frontier, Xuanzong gave his frontier commanders military governorships (*jiedushi*), weakening centralized imperial control over the Tang Army. One northwest frontier general of Turkish extraction, An Lushan, took advantage of his new position and rebelled, ordering his 160,000 veteran troops against the home army. The resulting An Lushan Rebellion (755–763) witnessed the seizure of the capital of Chang'an and the flight of the imperial court south to Sichuan. Order was reestablished in 763 only with the assistance of non-Chinese allies.

In the post-An Lushan climate, later Tang emperors created the "Divine Strategy Armies" to counterbalance the power of the frontier governors, placing palace eunuchs in command, but

even this contingency failed as the eunuch generals grew increasingly powerful until the end of the Tang dynasty in 907. Eunuch control over native Chinese armies ended in the Five Dynasties period (907–960), a politically unstable but militarily successful era characterized again by the centralization of the military under imperial control and the expansion of Chinese territory.

Thought and Religion

Theme 7 discusses the principal religions and philosophies during the Age of Expanding Regional Civilizations, 300–1000 CE.

Throughout much of history, especially since the rise of agricultural societies dominated by cities and the appearance of extreme class divisions and slavery, humans have sought comfort in the solace of religion. Religion, or a sense of the sacred, permeated every society and culture in the first millennium CE, as in other periods of history. However, the period from 300 to 1000 was not simply a time of religious stasis; rather, it was a protean period during which there was much religious ferment and new religions emerged. In this time period religious traditions developed that simultaneously divided and united humanity from then until modern times. During this period, today's great world religions (Christianity, Islam, modern theistic Hinduism, and Mahayana Buddhism) were largely shaped.

At the beginning of the Age of Expanding Regional Civilizations, Hinduism, Buddhism, and Confucianism were the chief religious categories in the eastern part of the Afro-Eurasian ecumene, while Zoroastrianism and Christianity would soon dominate the western part. In the fourth century, Christianity became the leading religion of the Roman empire, while the Sassanian empire, the other great power of western Eurasia, embraced Zoroastrianism. Islam emerged in the seventh century and grew at the expense of both Christianity and Zoroastrianism. After the rise of Islam in the seventh century, Zoroastrianism withered to insignificance, and Islam far surpassed Christianity in geographical extent and numbers of adherents and by 1000 CE was poised to overtake Buddhism as the world's leading religion in number of adherents.

Mahayana Buddhism was the world's leading religion in terms of geographical extent and number of adherents during the seven centuries before 1000 CE. It dominated or was a principal religion in most of East, South, and Southeast Asia, an area that had the preponderance of the earth's population and wealth. However, the category "Buddhism" includes as much religious diversity, especially in theology, as the three Western, or Abrahamic religions—Judaism, Christianity, and Islam—combined.

At the beginning of this period Buddhism was also a strong presence in central Asia but by the mid-ninth century Islam began to replace Buddhism as the dominant religion in central Asia.

In India, the land of its origin, Buddhism was still strong in 1000 CE, especially in Bengal, Kashmir, Punjab, and Bihar, but in a few centuries, Islam would replace Buddhism in these areas too.

The kingdoms of Southeast Asia utilized both Buddhist and Hindu rituals for their court ceremonies, but these religions did not significantly modify the popular religions for many centuries.

The expansion of Mahayana Buddhism out of its Indian origins began in the early centuries of the Common Era. This time period witnessed a great flowering of Indian civilization, especially in the Gupta period. During this Age of Southernization, India was the great fount of innovation for much of the Afro-Eurasian ecumene. It was a city on a hill, the beacon from which new technology, science, mathematics, philosophy, and especially the Buddhist religion radiated. The prosperity of northern India stimulated trade with its neighbors, especially seaborne trade with Southeast Asia and across the Indian Ocean and up the Persian Gulf and Red Sea to Persia and the Roman empire and overland trade to central Asia and through central Asia to China. Buddhist missionaries accompanied the merchants and established monasteries in central Asia and China as well as most of the lands of Southeast Asia. India was also the religious pilgrimage locus par excellence, as witnessed by Chinese and other pilgrims to India such as Faxian and Xuanzong.

Central Asian merchants brought Buddhism to China as early as the first century CE, but it was not until the third century that the Indian faith took root among the Chinese masses, spreading rapidly among the

Its appeal was similar to that of Christianity in the Roman empire at the same time: Mahayana Buddhism, like Christianity, offered salvation to the downtrodden and exploited.

common people during the Period of Disunity (220–589 CE). Its appeal was similar to that of Christianity in the Roman empire at the same time: Mahayana Buddhism, like Christianity, offered salvation to the downtrodden and exploited. In China, Buddhism was often conflated with Daoism, much as Christianity shared the appeal of Mithraism and other salva-

tion religions that abounded in the Roman empire in the early centuries of the Common Era. Although Buddhism entered China as a foreign religion, within a few centuries distinctly Chinese Buddhist traditions, especially Amitabha (Pure Land) and Chan (Zen), emerged.

Imperial and royal governments co-opted religions for political purposes, especially Christianity and Buddhism. These religions became arms of state power. Governments and religions supported each other in several ways. State power not only provided protection and status for the leaders of favored religions but also provided the favored religion with wealth, especially land and bonded peasants. Governments often supported the favored religion against its rivals, prosecuting and often killing or at least marginalizing religious dissenters and nonconformists.

Though favored religious organizations profited by their symbiotic relationship with government power, governments profited as much. Religions legitimated governments by teaching that the state was divinely sanctioned and that the rulers were surrounded by a divine aura. Thus, Catholic Christianity legitimated the Kingdom of the Franks/Carolingian empire, just as Mahayana Buddhism lent legitimacy to the Sui and Tang dynasties of China, and Hindu Shaivism and Vaisnavism did the same for kingdoms in southern India and Southeast Asia.

Indeed, one of the principal attractions that dominant religions had for emerging states is the legitimacy gained by these new kingdoms. For example, the rulers of Korea and Japan adopted Buddhism, in part, to strengthen their mantles of legitimacy. For like reasons, Georgia, Ethiopia, the new Germanic kingdoms of Europe, and Kievan Rus converted to Christianity. Many other new states followed similar courses. When these emerging states adopted a new religion, they imbibed the culture, the literature, and the view of history—in fact, the complete aspects of civilization—that any world religion carried. Buddhism carried Chinese civilization to Korea and Japan. Buddhism as well as varieties of Hinduism transmitted Indian civilization to Southeast Asia, while Christianity served as a vector for Mediterranean civilization in northern and eastern Europe. Until modern times (ca. 1500 CE), the religion that was the most widespread vector of a civilization, however, was Islam.

New states also benefited from the bureaucratic expertise of the clergy and monks of the newly adopted religion. North European kingdoms relied on Catholic monks, and Rus and other East European kingdoms made use of Orthodox clerics. In the Japanese and Korean realms, Buddhist monks played similar roles.

The Roman empire and all subsequent empires and states throughout the western half of the Afro-Eurasian ecumene identified themselves with intolerant state religions that demanded and enforced orthodoxy and orthopraxy (correct doctrine and correct ritual). In the Roman empire and its successors the state religion was Christianity as defined by the Seven Ecumenical Councils (325–787 CE), and Sassanian Persia enforced an intolerant form of Zoroastrianism although, for political reasons, it tolerated Assyrian Christians. A large, but only partial, exception to the claim of universal religious intolerance during this period is the Muslim states. While Christians, Jews, and Zoroastrians were tolerated, they were forced to accept an inferior position as *dhimmi* (people of the contract) and were subject to heavy taxation and humiliating restrictions.

While all early medieval states were legitimated and supported by an organized religion, religious heterodoxy (“other,” or deviant, doctrine) could be a serious danger to any regime. Dissenting sects, such as the Monophysites in the eastern Roman empire, Daoist sects in China, or Shias and Karijites in Islamic lands, gave religious coloration to widespread rebellions that shook and sometimes toppled powerful dynasties. For this reason, most states sought to enforce religious orthodoxy and were vigilant in rooting out heresy.

In most early medieval religions, there was a sharp division between the clergy and the laity. (Islam was the great exception to this.) The clergy were the class of religious specialists, the priests, monks, and nuns, while the laity were the common believers who supported the religious specialists. Monasteries were special communities of religious specialists. Their function was to perfect the spiritual lives of their inhabitants but also to pray and to intercede with the deity in favor of the society. The earliest monasteries were established in India, and the Buddhists had many. Buddhist missionaries persuaded rulers to establish monasteries in the lands surrounding India, and soon other

religions, such as the Manicheans and the Daoists, established their own monasteries. In the late third century, a Manichean monastery is reported to have existed in Rome. In the third century, Christian monasteries were founded in the Roman empire. Monasteries, both Christian and Buddhist, rapidly accumulated wealth and political power. They were influential in almost all areas of their societies but especially in education. The Buddhist monastery-academy of Nalanda (in Bihar, India) is said to have had 10,000 students. Monastic expansion in China received an abrupt and lasting check when the emperor, in 841–845,

Monastic expansion in China received an abrupt and lasting check when the emperor, in 841–845, decreed the dissolution of thousands of monasteries and the defrocking of a reported one million monks.

decreed the dissolution of thousands of monasteries and the defrocking of a reported one million monks.

In Islam, the clergy was much less distinct than in most other religions. The Quran does not mention clergy except to say that it wanted no monks. But over the centuries, classes of religious specialists did emerge. Toward the end of this period, the ulema (the learned), religious scholars and juris-consultants, constituted one such class.

Sufi mystics were another class of religious specialists that arose in Islamic societies by the end of this period. Mysticism, here defined as ecstatic religious experience, manifested itself in most religions. Buddhist and Hindu mysticism in this era emerged in new transformative movements and sects: Bhakti devotionism in Hinduism, Tantricism in Hinduism and Buddhism, Amida Pure Land Buddhism, and Chan Buddhism.

The histories of religions in North Africa and Eurasia show a rough parallelism, particularly during the first millennium of the Common Era. In the first century of the Common Era, religions promising a universal savior, such as the Mahayana Buddhist bodhisattva, Avalokitesvara (Sanskrit for “Hearer of the World’s Cries”), emerged and grew in the early centuries of the Common Era. As China’s Han dynasty was collapsing in the third century, Mahayana Buddhism, with its promise of savior bodhisattvas, spread rapidly among all classes of Chinese, and Avalokitesvara became the Chinese Guanyin. In the fourth century, as the northern Chinese heartland suffered pillage and destruction by barbarian horsemen, faith in another Buddhist savior became prominent: Maitreya, the Buddha of the future. Repeatedly, desperate peasants rebelled under leaders who proclaimed themselves the incarnation of Maitreya.

In the Roman empire, several new religions competed for popular favor in the first centuries CE. Most centered their teachings on a universal savior who saves sinful humanity by suffering a painful death and is then resurrected. In the fourth century, Christianity emerged as the winner of this competition and suppressed all of its rivals.

Christianity’s triumph in the Roman empire parallels the contemporaneous triumph of Buddhism in China. There, by the seventh century, Buddhism evolved into distinctly Chinese forms, including Chan (Zen) and Amitabha (Amida) Buddhism. Amitabha or Pure Land Buddhism, like Christianity, offers surcease from the sufferings of this world as well as a Pure Land, or heaven, in the afterlife.

Muhammad in Arabia and Adi Shankara in India were the two most influential religious leaders in this era. Muhammad was the superhero of this period who not only founded a new world religion but also established a great empire, which was one of the age's superpowers, as well as a new civilization that spread throughout the Eastern Hemisphere.

While Pure Land Buddhism was developing in China and the Islamic civilization was growing in West Asia, bhakti, a movement of ecstatic devotional love for chosen deities, primarily Shiva and Vishnu, emerged from Tamil, or southern India. During the first millennium CE, a triangular struggle among Buddhists, Jains, and Hindus for India's allegiance raged. By 1000 CE, varieties of Hinduism triumphed, partly because of the destruction of Buddhist monasteries by Muslim invaders but mostly because of the bhakti movement and the reformulation of Hinduism by religious figures such as the ninth-century holy man Adi Shankara, who was also one of India's most influential in a crowded field of theologians and philosophers.

India was the world's leading hotbed of spiritual speculation during this era. The leading schools of Indian philosophy are known as Vedanta ("the culmination of the Vedas"). There were many varieties of Vedanta, of which six are recognized as orthodox, but the leading school was and is Advaita (nondualism), which Shankara championed and which is still identified as *the* philosophy of India.

During the same time, philosophic speculation in China was absorbed with the process of adapting the rather alien thought structures of Buddhism to Chinese realities. After the collapse of the Han dynasty, the Han Confucian-Legalist synthesis, basically a political philosophy, was widely abandoned for the more consoling Buddhist formulation. It was not until after the fall of state-sponsored Buddhism in the middle of the ninth century that Han Yu and Li Ao began the synthesis of Daoist and, especially, Buddhist concepts with Confucian political philosophy that would emerge as neo-Confucianism in the early Song dynasty.

As far as Christian speculative theology during this era was concerned, the only philosophic/theological work that still resonates is Augustine's *City of God*. During the fourth century, the Monophysite controversy concerning the nature(s) of Christ convulsed the Christian world, but from then until the eleventh century, philosophic speculation in Christian Europe was a neglected enterprise.

Like the Christians after the fifth century, the early Muslims discouraged philosophic speculation. However, after coming in contact with the philosophies of the Mediterranean world and beyond, they attempted to synthesize Hellenic, Hellenistic, Persian, and Indian thought and to make this synthesis compatible with the teachings of the Quran. The eighth century saw the development of the Mutazilite school, a theological movement that centered much of its thought on the problem of predestination versus free will. During the ninth and tenth centuries, a veritable explosion of philosophic speculation emerged with the increased translation of Greek and Hellenistic philosophic texts. These were the centuries in which the Kalam and Falsafa thrived and when the great Arab and central Asian polymaths, al-Kindi and al-Farabi, worked.

For nonliterate cultures and civilizations outside of the Afro-Eurasian ecumene, our knowledge of their thought and religious systems during this era is much less complete than it is for the Afro-Eurasian ecumene.

We can glimpse ideas concerning the sacred in Africa south of the Sahara by inferences made by scholars using the tools of linguistic analysis. By this method, scholars have reconstructed some of the religious history of early medieval Africa south of the Sahara. The religious focus of West and central Africa south of the Sahara involved worship for and propitiation of the ancestors. Peoples in this region had a vague notion of a creator god, but this deity was a distant and indistinct figure, scarcely a subject of worship. As the Bantu spread from West and central Africa, they took with them their ancestor-centered religion with its indistinct creator god, but as they moved into the Great Lakes area of East Africa at the beginning of the early medieval age, they assimilated grain-cultivating and cattle-herding Nilotic and Cushitic groups who worshiped a sky god as the supreme deity. The resulting religious change flowed back westward along the migration routes. Powerful and sometimes malevolent deities appeared in West, central, and East Africa, and witchcraft became more prevalent.

With the rise of population densities, the concept of sacred kingship, in which rulers and their families were invested with mystical power, began to manifest itself. This was especially true of the Nri kingdom in the area of modern Nigeria. But one of the most significant reli-

With the rise of population densities, the concept of sacred kingship, in which rulers and their families were invested with mystical power, began to manifest itself. This was especially true of the Nri kingdom in the area of modern Nigeria.

gious changes in Africa south of the Sahara began to manifest itself toward the end of our period, when Muslim Berber and Arab merchants began to spread the Islamic faith in the West African savannas and the East African (Swahili) littoral.

For the Americas and Polynesia, our knowledge of religion during the early medieval age should be most complete for Mesoamerica because the cultures of this region were literate. Unfortunately, most

of their writing is lost, largely due to Spanish Catholic suppression in the sixteenth century, and the little that survives dates from the immediate Pre-Contact period, 500 years after the collapse of the Classic civilizations. The best-known Mayan religious writing, the *Popul Vuh* creation myth, is from the Post Classic Period, several centuries after this period.

The inscriptions on the monumental architecture of the Mayan Classic Period, which in recent years have been deciphered, indicate that the rulers of the Mayan cities were enveloped in a sacred aura and that a principal function of religion in Mesoamerica as in Eurasian societies was to glorify and legitimate the ruling order. The Mayan rulers were the intercessors between their cities and the supernatural powers that were thought to control their world.

We do not know if the Maya or the other peoples in Mesoamerica during this period had an organized religion with a professional priesthood. We cannot be sure that they insisted on a theology that they regarded as orthodox. But it is likely that the Mesoamericans of the Classic

Period, like their successors in the Post Classic Period, believed that the history of the world was cyclic, with the universe flourishing and then being destroyed in each cycle.

For the religions of the urban-agrarian civilizations of the Andes, we can only draw inferences from archaeological artifacts. Archaeologists speculate that in the period 300–1000, there were two religious traditions in the Andes, the Northern and the Southern traditions. The Northern, or Moche, tradition was male-centered and emphasized warfare and human sacrifice, whereas the Southern tradition, the tradition of Wari and Tiwanaku, was more centered on ancestor worship and preservation. In the Southern tradition, an androgynous god, sometimes called the Two Faced Deity, was prominent.

During the early medieval age agricultural peoples, dominated by cities all over the world, were divided by more or less extreme class inequalities. In all such civilizations, the dominant class imposed or used a religion to legitimate its position and power. Most organized states were kingdoms during this period, and a major function of the dominant religion in these kingdoms was to envelop the ruler with a supernatural aura. This was also true of most chiefdoms, such as those of the Hopewell and Pueblo civilizations of North America, as well as of Polynesia.

—*Wilfred J. Bisson*

■ Introduction: Non-Eurasian Religions

Since most non-Eurasian peoples had no written literature in this period, it is difficult to understand much about their religions in the first millennium CE. Archaeologists have made some inferences from the artifacts of this period, and ethnohistorians have done some fascinating work in linguistic analysis of African languages, but the pictures that emerge are vague, the conclusions arrived at are extremely tentative, and most statements on the subject are based largely on conjecture. Where there is literary evidence, as in the case of the Maya, our understanding is on firmer ground, but it is still evolving.

—*Wilfred J. Bisson*

Andean Religion

Pre-Columbian religions in the Andes stem from one of two regional traditions clearly visible during this era. A Northern Tradition developed along the northern coast of Peru and may have reached inland as far as the Marañon Valley. A Southern Tradition developed along Peru's

southern coast, reaching up into the High Sierras and down into what is today Chile and Argentina. Overlap in the iconography of these two traditions probably stems from the far-reaching and early influence of the Chavin culture (800–200 BCE).

The Northern Tradition, as exemplified by the Moche culture (100–750 CE), incorporated at least two separate cults, sects, or distinct aspects, one of which was closely tied to elite power and control. That practitioners of this tradition separated these aspects is evidenced by the different use of media in which people conveyed important religious messages.

Most perplexing to modern observers is the male-centered cult aspect of the Northern Tradition. It is this tradition that produced the famous pornographic pottery. These are sculptural ceramic pieces that exhibit males with oversized phalluses or couples, including two males, engaged in a variety of sexual activities. Because the sexual acts depicted are rarely procreative, this may represent a cult of male virility rather

➤ ARCHAEOLOGICAL PROBLEM—IDENTIFYING SUPERNATURAL BEINGS

How can we tell if a religious image represents males or females, mortals or supernatural beings? In the Andean region artists used certain conventions fairly consistently to indicate to viewers what type of character they were seeing. By deciphering this system of representation, we can get a better idea of what ancient religions were all about.

Ancient artists defined supernatural beings in two ways. First, they showed some supernatural beings with bodies compounded from more than one type of animal or combinations of human and animal parts. These characters might have canine or feline heads and human bodies or combinations of feline, bird, or fish attributes. Figures that looked exactly like ordinary human beings also occurred. To distinguish them from mere mortals, artists showed them with bared teeth and prominent fangs in their upper and lower jaws.

Telling males and females apart is more difficult for us today than it may have been to the original viewers. Today, when viewing these artifacts, we rely mostly on indicators of physical or sexual characteristics and the ways in which they are associated with other attributes. Wari and Tiwanaku pottery, for example, often illustrated men sporting various configurations of facial hair in combination with particular garments such as tunics and four-cornered hats. Women, when they appear in Wari and Tiwanaku art, dress differently, often displaying a shawl draped over their shoulders or a dress supported by large pins conveniently placed over where the breasts would be.

—Jo Ellen Burkholder

than one of fertility, strictly speaking. Spanish chroniclers later reported similar behavior from the later Chimú culture, suggesting long-term continuity in these ideas in the north.

The Northern Tradition also embraced an elite cult of ritual warfare and sacrifice. As early as the second millennium BCE, religious art of the north depicts battle and its consequence. Winners sacrificed losers by disemboweling or dismembering them. By Moche times, artists depicted battles between human pairs of different ethnicity or between pairs of humans and supernatural beings. The narrative style of Moche art

makes it clear that losers were stripped, bound, and sacrificed with a semicircular knife called a *tumi*. An entourage of priests then offered the blood of sacrificial victims to a high-ranking elite seated on a covered throne. Knives of various metals and cups such as those shown holding sacrificial blood commonly appear in elite tombs.

The Southern Tradition incorporates the cultures of Paracas, Nazca, Pukara, Wari, and Tiwanaku. As in the case of the Northern Tradition, data supports the existence of several distinct cults, sects, or aspects of this tradition. It is out of this tradition that the preservation and worship of ancestors, as seen in the Inca culture, probably emerges. Also mirroring the Northern Tradition, some aspects of the Southern Tradition were more connected to elite power and control than others. Consumption of hallucinogenic and intoxicating substances in the form of snuff and/or drink may have played a part in many aspects of religion or may have existed as separate cults.

Most notably, the Southern Tradition incorporated a figure known as the front-faced deity. People portrayed this deity in different ways, as a floating head with rayed projections, as a standing anthropomorphic being (both seen in Pukara, Wari, and Tiwanaku), and perhaps as a splayed or flying supernatural being (seen in both Nazca and Paracas). Association of these representations with fancy pottery vessels, especially in the case of Wari and Tiwanaku, suggests a connection between the front-faced deity and elite drinking rituals. Researchers have identified both male and female forms of this deity, although representation of gender is not consistent across time and space. The dual or androgynous nature of this deity constitutes a strong reason to link it to the later Inca deity known as Viracocha.

As with the Northern Tradition, a fertility cult seems to have coexisted alongside of the front-faced deity cult. Unlike their northern cousins, however, people of the Southern Tradition focused on female fertility rather than male virility. Paracas (800–200 BCE) expressions of this include depiction of oculate beings—anthropomorphic or zoomorphic forms with large concentric eyes—that contain smaller versions of the same figure inside the abdomen. Nazca peo-

ple (200 BCE–1000 CE) first made small figurines of both males and females and placed later emphasis on robust female forms with their genitalia emphasized. In the highland cultures of Pukara and Tiwanaku, people expressed concerns with fertility through a connection between human females and domesticated camelids, especially llamas. Female images become rare in Tiwanaku times (600–1000 CE), but small votive llama figurines become common.

Trophy heads form another focus of the Southern Tradition. Researchers commonly apply the term “trophy head” to any human head with no attached body. Strictly speaking, however, true trophies are human heads that have been intentionally removed from the body and preserved, usually by removing the brain, securing the eyelids and lips with thread or cactus spines, and attaching a cord with which to suspend it. Nazca people clearly produced and kept true trophy heads. Other cultures associated with the Southern Tradition may only depict human heads. Often, heads appear to be held by the hair rather than a cord, and postmortem treatment of the mouth, eyes, and brain is unclear. Frequently it was a supernatural being who clasped the head in one hand and a sacrificial knife in the other. Some suggest that decapitation rituals may have had stronger connections to ideas of agricultural fertility than to a cult of male warfare, as seems the case for the Northern Tradition.

The complex practice of ancestor worship also seems to emerge from the Southern Tradition. Three things distinguish this practice. First, people placed at least some of their dead in tombs that could be reopened and revisited many times without fear of damaging the preserved remains. Second, people positioned ancestor burials in locations where the ancestors could be feted and propitiated. Third, people made repeated offerings to ancestors, not just at their death or burial but on repeated occasions thereafter. Wari and Tiwanaku cultures probably had the beginnings of recognizable ancestor worship, but the practice matured and spread throughout the Andes. By the time of the Spanish Conquest, ancestor veneration was common in the Andes.

Religious Change in East, Central, and Southern Africa

The arrival of Bantu-speaking peoples to East, central, and southern Africa, circa 300–1000 CE, transformed the religious philosophies of these regions. A religious transformation during this period reflected cultural syncretism and also changes within various Bantu-speaking societies.

By 300 CE most Bantu-speaking peoples worshipped one creator God who was often believed to be distant from people. The proto-Bantu word for God was “Nyambe,” and it is still used in the western Bantu-speaking regions of Africa. The word came from an old Niger-Congo verb root that meant “to begin.” This meaning fit perfectly with the Bantu belief in God as “the Creator Who made the world begin.” Around 400 CE Bantu-speaking peoples in East Africa developed a new term for God, “Mu-lungu.” This new term was derived from the old Bantu verb “-lungu,” which meant “to become fitting, become straight,” and added a new attribute to God as the “Supreme Example of Righteousness.”

Day-to-day worship involved paying homage to one’s ancestors and later to various territorial spirits. While God was respected for creating the world, neglecting ancestors could have disastrous effects for a person, his or her family, or the community at large. People would placate their ancestors, and in return they expected help in dealing with life’s problems.

A major source of evil in the Bantu religious philosophy was human beings who were

➤ ONE GOD—SHE/HE

European missionaries called Bantu-speaking Africans “pagans,” but in reality they were monotheistic since they and their ancestors believed in one Creator God for almost 10,000 years. While the role of God varied among the peoples of East, central, and southern Africa, the one constant was that God was never gendered. God could have female and male attributes but was considered to be either both genders or beyond gender. Even the words used to describe God are without gender markers. It took the arrival of missionaries and colonial scholars in the nineteenth century to make God male. As they translated African religious traditions and myths, they missed both linguistic and oral tradition evidence to the contrary and made the God of Bantu-speaking peoples masculine.

—Christine Ahmed-Saidi

consumed by feelings of malice and jealousy. “Bu-logi” was the term for this source of evil, inadequately translated as “witchcraft.” Bantu-speaking peoples called on the Baganga, or a group of skilled practitioners of these medicinal practices, to diagnose, treat, and even prevent individuals from falling under the spell of a “witch.” Ironically, the fear of witchcraft among these societies encouraged social equality. Since most cases of witchcraft involved envious or jealous individuals, people tended to distribute any wealth they had rather than hoarding it. They would also ensure good relationships with their neighbors and distant relatives through the sharing rather than the stockpiling of food.

In East Africa, Bantu immigrants came into contact with the Southern Nilotes, who believed that the sky and rain were a single spiritual force or presence. By 300 CE in the Great Lakes regions of East Africa, the Bantu-speaking peoples of southern Nyanza had invented a new word for God, “li-uba,” that was an old Bantu term for “sun.” As they moved south, the Bantu-speaking peoples continued to add sky and rain attributes to the Creator God.

The BaTwa and the Khoisan-speaking peoples also had an effect on the religious beliefs of the arriving Bantu immigrants. The Khoisan be-

lieved that only people in trances could communicate with the spirit world. Many Bantu-speaking peoples adopted this belief, and spirit possession became an important aspect of their religious practices. In any region where there was a significant BaTwa population, religious worship required that these gathering and hunting peoples participated.

In east-central Africa, circa 500 CE, the decentralized and matrifocal Bantu-speaking peoples developed a new term for the Creator God, “Leza.” The word was derived from an older Bantu root, “-lel-,” meaning “to bear, take care of (child).” Its literal sense appears to have been “to nurture (especially a child).” Calling God by such a term likened the activity of the Creator to one of the major activities of a woman. Equally significant, the derivation of Leza conveyed a new and innovative conceptualization of the Creator as an active presence, like a mother, rather than as a distant First Cause. In the Botatwe group, God was called by such alternative names as Lubumba, “the molder, one who shapes or molds,” as a woman molds her pot. The neighboring Bantu-speaking peoples also adopted the word “Leza” and the female attributes of the Creator but added the sky imagery. Thus, the term “Leza” could now mean God, rain, and lightning.

Political and social changes in these regions also affected the transformation of religious beliefs. As the population grew in the Great Lakes region, so did the pressure on the land and struggle over control of resources. The chief held a new religious role as intercessor in order to prevent departed ancestors from harming the living. Many of these ancestors became territorial spirits, and the chiefs who appeared to control or appease these spirits became the political leaders of the emerging centralized polities.

In the early ministates along the Congo River, circa 1000 CE, the rulers had become the mediators among the people, their ancestors, and the local territorial spirits. This pattern was repeated throughout the region in the centralizing societies. Common people were no longer able to directly pray to the ancestors or even to God. Instead, they needed intercessors who in turn grew more powerful.

Classic Maya Ideas of the Sacred

Religion is a difficult concept to unravel in prehistoric societies. The imagery and writings of Classic Period Maya were never intended for modern audiences. Their messages were intended for people who already knew the conventions, stories, and background essential for fully understanding their world. Nevertheless, major advancements in the decipherment of Maya hieroglyphs along with an increased data set have worked together to bridge many of the deficiencies in our understanding of Classic Maya religion.

The term “religion” is probably a misnomer. Ancient peoples such as the Maya did not classify their world into rigid distinctions between religious activities and nonreligious life. For them, life was religious. Ritual permeated their being and gave flavor to the world around them. From planting corn to harvesting vegetables, every action was a ritualized activity.

There is no evidence that the Classic Maya had a system of orthodoxy. Each kingdom had a corpus of beliefs that paralleled those of other nearby kingdoms but without an ecclesiastic body that canonized them. The incredible coherency of their beliefs is evident in the archaeological record. Principal legends and individuals can be identified by costume and activity from materials dating from 300 BCE through 1600 CE. While many of the smaller legends and stories disappeared or changed over time, the core had not.

Illustration after a figure in a Maya manuscript depicting Itzamná, the principal deity of the Maya. (EclectiCollections/Fotosearch)

A primary concept to understanding the Classic Maya world is that everything is imbued with vitality. Rocks, mountains, carvings, idols, fish, plants, animals, and people are all vital beings. The earth itself was portrayed as either a crocodilian monster or turtle. Both are animals capable of movement, and earthquakes occurred when they moved. Likewise, an image of a king partook of his vitality and became the king to an extent. An image of the corn god was the corn god. It shared his vitality, his essence, and hence was a god. Even hieroglyphs had their own vitality. The unread word was actually alive and awaited an opportunity to be read. For these reasons, archaeologists frequently find defaced monuments dedicated to kings. The eyes, nose, and mouth of the figure were vandalized in the past. This illustrated that someone wanted to destroy the king's essence and presence.

In addition to general vitality, some beings had extra vitality that set them apart from the rest. These were gods and royalty. Major gods

THE POPOL VUH

The Popol Vuh is a Quiche Maya account of the creation of the world and some of the activities of the supernaturals at that time. Although the book is a sixteenth-century document, many of the stories within it were known to the Classic Maya. The first section describes the multiple creations of the earth. The second section concerns the exploits of a series of twins. The twins, Hunahpu and Xbalanque, defeat the Lords of the Underworld in a series of contests. They are common symbols of kingship in Classic Maya lore. All together, the *Popol Vuh* chronicles Classic Maya legends faithfully. Below, the *Popol Vuh* tells of the origin of humans:

“There was only immobility and silence in the darkness, in the night. Only the Creator, the Maker, Tepeu, Gucumatz, the Forefathers, were in the water surrounded with Light. They were hidden under green and blue feathers, and were therefore called Gugumatz. . . . Then while they meditated, it became clear to them that when the dawn would break, man must appear.”

were manifestations of nature’s primal forces. Beings such as Chaak and K’awil represent the chaotic forces of nature. For example, Chaak (god B) was a storm god who rained lightning and thunder down upon the earth. Yet there were also small gods who were worshipped locally. The identity and role of small gods are difficult for archaeologists to reconstruct because of insufficient information. Perhaps they were aspects of a greater god, ancestors who became intermediaries to the gods, or even gods themselves.

The pantheon of major gods was not large. Itzamna was the name of the old creator god. His equally aged wife or consort was Ix Chel, goddess of midwives and healing. Kinich Ahau (god G), or the sun god, warmed the earth during the day and changed into a jaguar at night as he returned to his morning place. The maize god, pos-

sibly called Hun Nal, was a major element in Classic Maya representation. He embodied resurrection and growth. Yum Cimih (god A) was the patron of death and the underworld. In addition to these well-known entities, other supernatural entities were also depicted but are not as well understood by archaeologists. Contact period documents provide information about minor gods but probably do not give the full picture of their importance to Classic Period civilization. For example, god C, possibly Ah Chicumek, was associated with the north star, merchants (during the post-Classic Period), and with the rain god. God K was associated with rulership and scepters. Finally, dwarves and twins were held in esteem by the Classic Maya. Dwarves were associated with underworld activity, and twins were well represented in their legends.

Royalty was also holy (written as “k’uh” in the hieroglyphs). While stopping just short of being gods themselves, Maya rulers certainly partook of godly essences. Their very names indicate godlike aspects that were added to their essence. They protected the god-images of the city, supervised activities generally, and were essential to the well-being of the kingdom. They were the kingdom in some instances. They entered into the gods’ homes and communed with the supernatural on behalf of their subjects. There was also a belief in a duality of soul for some individuals. A king might have had attributes of a jaguar, for instance. Beliefs about dual natures are still common in Mesoamerica and South America and may have originated with the Olmec civilization.

An underlying theme of Mesoamerican religious belief was the idea that humans and gods entered into covenant relationships. The gods, after several miscues, created humans to worship them from corn dough. The privilege of creation, wherein mankind possessed physical bodies and life, carried with it an obligation to return vitality to the gods in the form of sacrifice. Thus, food for the gods was offered up. These sacrifices included incense smoke, blood, and the occasional captive. The Maya did not sacrifice humans to the same degree as the Aztec, but it did occur. Royalty, being close to the gods, were especially required to feed the gods with their own blood. Luckily, these offerings could be given while living through bloodletting

from ears, tongue, and especially genitalia. These offerings were then burned and the essence ascended to the gods. There is also evidence that substitutions occurred. Red pigment would sometimes be offered instead of blood.

However, when sacrifice failed and the gods were not listening, some communities would chasten their gods by holding their images responsible for the chaos they endured. They would put the gods in direct sunlight or hold them upside down to compel them to uphold their side of the covenant. If this did not work, perhaps the Maya would look for another god to sustain them in their need.

■ Introduction: Eastern Eurasian Religions

The eastern Eurasian religions included in this discussion are those of China and India: Confucianism and Daoism for China and Hinduism, Buddhism, and Jainism for India. This does not by any means exhaust the list of religions practiced in this period in eastern Eurasia; one thinks also of Japanese Shinto, Korean Shamanism, and Tibetan Bon in this connection.

This period preeminently witnessed the rise and spread of Mahayana Buddhism in India and then from India to central Asia and China and from China to neighboring countries such as Korea, Japan, and Vietnam.

In China, Confucianism had become, in the third and fourth centuries, somewhat discredited by its association with the defunct Han dynasty. Mahayana Buddhism became the favored religion of several succeeding Chinese dynasties, including the Sui and the Tang, until the 840s, when a powerful antiforeign movement began its serious decline. In the late ninth century, Confucianism, in the guise of neo-Confucianism, began to regain favor. While at its peak of acceptance Buddhism had become so closely identified with Chinese culture that when Buddhist missionaries went to Japan and Korea, they brought Chinese civilization with them. In these lands, too, Buddhism became the favored religion of the rulers.

In India, Buddhism did not become as powerful as in China during this period. Instead, there was a three-way struggle for India's religious allegiance among Vaishnavite/Saivite Hinduism and Buddhism and Jainism. In spite of the Buddhist's command of the intellectual heights at the great monastery/universities of Takshashila and Nalanda, Hinduism, by the ninth century, won the contest with the development of *bhakti*, religious devotionism that generated an intense love for the deity. By the tenth century, Buddhism was confined to the northwest and northeast of India, and in the eleventh century the destruction of the Buddhist monasteries led to the virtual extirpation of Buddhism in India.

In the early and middle centuries of the first millennium CE, India exported both Buddhism and Hinduism to the southeastern mainland and the Indonesian archipelago. By the end of this era (1000 CE), the royal courts in mainland Southeast Asia accepted both Hindu, usually Saivite, and Mahayana Buddhist rituals and personnel, but in the twelfth to fourteenth centuries, Theravada Buddhism, brought by missionaries from Sri Lanka, became the official religion of most mainland Southeast Asian lands, with the notable exception of Vietnam.

In the Indonesian archipelago, Srivijaya and the central Javan kingdom of the Sailendras

adopted Mahayana Buddhism, but their rivals in East Java and Bali were Saivite Hindus.

—Wilfred J. Bisson

Hinduism and the Heterodoxies, 300–600 CE

Hinduism cemented its role as the orthodox religion in India around 300–600 CE, while its competitors, Jainism and Buddhism, were relegated to the position of heterodoxies. Interaction among the three religions was marked by three main developments: the flourishing of classical culture in northern India during the Gupta and post-Gupta political dynasties (300–700 CE); a more diffuse distribution of power among the various social classes (castes), conflict between which was indelibly linked to Buddhism's and Jainism's rise; and the growth of more popular, theistically oriented expressions of religiosity in all three traditions.

During the Gupta and post-Gupta eras of northern India's Classical Period, the rise of devotionally oriented theism is the major religious development in Hinduism. Textually this development is expressed in the two great literary epics of Indian tradition, the *Ramayana* and *Mahabharata*, with the *Puranas* (fifth through tenth centuries CE) further extending the theism first expressed in the epics. Theologically, the Forest-Books (Aranyakas) and Upanishads of the Vedic corpus offer a monistic metaphysics, which continues as the basis of modern philosophical formulations associated with the Vedanta ("end of the Vedas"). The epics, however, offer a distinctly theistic vision centered on the two main incarnations (*avatara*) of the male god Vishnu, Ram and Krishna. According to this vision, Vishnu takes incarnation in these forms to restore the earthly and cosmic order (*dharma*), which is threatened by the forces of disorder personified in the evil protagonists of each tale. Moreover, in the Bhagavad Gita (9.12–30), which was inserted into the *Mahabharata* epic, Krishna serves as the spokesperson for a broader social vision and multiple paths to salvation that seek to appeal to women and the laboring castes (Shudra), whom orthodox Hinduism discriminated against. According to Indian tradition, there are 18 major *Puranas*. The *Puranas* were

instrumental in helping to spread the worship of the deities that comprise the contemporary Pan-Indian pantheon of the male gods Vishnu and Shiva and the goddess in her various guises. Artisans had perfected the sculpting of freestanding images by the second century CE, and it is speculated that growth in religious architecture in all three religions was connected with the need to house such images.

Jainism advocates strict asceticism for its monastic practitioners as a means of self-purification leading to spiritual liberation. As in early Buddhism, this led to a significant divide between the religion's laity and those who chose the route of monastic discipline. The core system of ethics in both Jainism and Buddhism advocates abstention from violence, dishonesty, misuse of sex, theft, and the use of intoxicants, although Jains stress instead nonaccumulation of material wealth as their fifth great vow. According to Jain tradition, the religion underwent a major schism into the two main sects of the white clad (Shvetambara) and sky clad (Digambara) during the reign of the Mauryan emperor Chadrugupta I (321–297 BCE) regarding the issue of whether or not its monks were permitted to wear clothes, with the latter opposed to this as a sign of shame and hence ego awareness. At the Second Jain Council of Vallabhi in the early sixth century CE the division between the sects was formalized, and the sacred canon of the Shvetambara sect was codified.

Buddhism experienced its period of most rapid growth between the second to seventh centuries and was likely the world's largest religion at that time. By the time of the Fourth Buddhist Council in the second century, missionary activity to central Asia and China had increased greatly, and the schism between the religion's two major schools, the Theravada and Mahayana, was recognized. The early centuries CE saw a great flourishing of Buddhist art and architecture in monuments such as burial mounds (stupas) and cave monasteries, including Ellora and Ajanta in central Maharashtra. Buddhist sculpture such as that of the early Mathuran school was created to adorn the exteriors of the stupas and cave monasteries and serve as focal points of worship in the latter case. Ellora and Ajanta are rightly famous as premier examples of cave

architecture during this period that combined monasteries for Buddhist monks and worship halls (*chaitya*). More than 20 cave temples dot the site, which is famous beyond its architectural importance for its beautifully painted murals in vivid colors. Many of the murals depict scenes from the narratives of the Buddha's previous lives (Jataka) and serve as visual scriptures.

Buddhist monastic centers cum universities continued to be constructed from these early models well until Buddhism's demise in its Indian homeland. The monasteries served as sites of higher training for members of the monastic communities (Sangha) as well as oases of culture for the laity. One such site was Nalanda in north-eastern India, which dates back to the second century CE. The Buddhist logician and founder of the Madhyamika school of philosophy Nagarjuna was said to have taught there. Two other great Buddhist teachers and scholars, Shantarakshita (ca. 705–788) and Atisha (982–1054), were also associated with Nalanda and played instrumental roles in bringing Buddhism to Tibet. Buddhism's concentration in these monastic centers, however, also contributed to the religion's disappearance from India. Nalanda was destroyed in 1198 as part of the Muslim Turks' overthrow of the Pala empire in 1162 and their eventual conquest of India's eastern region.

In the contemporary world, Theravada Buddhism is found principally in South Asia (Myanmar, Sri Lanka) and most countries of Southeast Asia; the Mahayana branch is the dominant form in East Asia and heavily influenced the third major form of Buddhism known as the Vajrayana (Thunderbolt Vehicle). The other major influence upon Vajrayana Buddhism was Tantric religion, which enjoyed a resurgence in India during the sixth century CE and eventually developed both Hindu and Buddhist forms. In the modern world, Tibetan Buddhism is the most widely known variety of Vajrayana Buddhism, although it can be found throughout northern Asia.

Forms of Early Buddhism— The Emergence of Mahayana

Broadly speaking, one can trace the emergence of three movements within Buddhism. The first occurred in the middle of the first millennium when numerous sects arose that interpreted the Buddha's teachings in diverse ways. Most of these sects also had their own monastic ordination lineages. The second broad movement was the rise of Mahayana Buddhism, a division that questioned and challenged the aims of early Buddhism. The third group under consideration here is Vajrayana, a form of Buddhism involving rituals and meditations rich in symbolism.

Mahayana ("Great Vehicle") Buddhism is not in itself a sect of Buddhism but rather a loose coalition of texts, ideas, and individuals who collectively comprise a reform of Buddhism that evolved over the first millennium CE. While the first explicit mention of Mahayana in inscriptions comes from the sixth century CE, the ideas that make up Mahayana thought were circulating as early as the first century CE. Given that in India there were no Mahayana ordination lineages, it is likely that those who explicitly considered themselves Mahayana Buddhists were an influential minority within the Indian Buddhism itself, despite the prominence of Mahayana thought and practice in East Asia.

The central concern dealing with salvation of Mahayana Buddhism was the bodhisattva, a figure motivated by compassion to vow to lead all other beings out of suffering to nirvana. Texts such as Chandrakirti's *Madhyamakavatara* (seventh century) and Shantideva's *Bodhicaryavatara* (eighth century) integrated Mahayana

THE COUNCIL OF LHASA

The Council of Lhasa, a series of debates held in Tibet at or around 792, provides insight into variations in the development of Mahayana. At issue was the nature of nirvana and the bodhisattva path. The Chinese Chan representative Mo-ho-yen argued that awakening occurred suddenly because all things are innately of the nature of the dharma. Heading the Indian delegation, Kamalashila argued for a gradual path to nirvana after spending lifetimes perfecting moral and spiritual qualities. The Indian side proved victorious in the debates, and as a result Indian Mahayana was to have the greatest influence on the development of Tibetan Buddhism.

—Matthew Bingley

philosophy with an elaborate framework of practice in which a bodhisattva progresses along ten stages to Buddhahood. Each stage marks the achievement of the perfection of different characteristics, most notably giving, morality, patience, effort, meditative absorption, and wisdom. Kamalashila's eighth-century *Bhavanakrama* (*Stages of Meditation*) expands on the dual virtues of wisdom and skillful means, the latter of which includes the abilities that the bodhisattva wields to aid all beings. In this ideal the bodhisattva criticized earlier sects of Buddhism as rewarding the selfish practitioner who strives to attain nirvana within patriarchal and socially stratified contexts that held monastic institutions in higher esteem than lay institutions. Mahayana authors referred to these earlier visions of Buddhism as Hinayana (Inferior Vehicle).

The central doctrinal concern of Mahayana thought was the perfection of wisdom (*prajna-paramita*). Rejecting the view that any dharma has any inherent existence, the Madhyamaka School taught that ultimately all phenomena are of the nature of emptiness (*sbunyata*). The philosopher Nagarjuna (ca. third century CE) taught that everything is empty; everything is merely an appearance or an illusion or like a dream. Similarly, perfection of wisdom texts such as the *Heart Sutra* and the *Diamond Sutra* taught that this perfection would lead to awakening through an insight into the nature of reality. The Madhya-

maka School believed that the world as ordinarily experienced was provisionally true until one discovered that all things were ultimately empty. This conventional distinction proved to be a point of contention between Nagarjuna's successors, such as Bhavaviveka (ca. 500–570 CE) of the Svatantrikas and Chandrakirti (ca. 600–650 CE) of the Prasangika. Despite philosophical differences over the extent to which reality can be considered empty, the notion that reality was ultimately an illusion proved to be the dominant idea within Mahayana Buddhism.

Some thought that Madhyamaka took the idea of emptiness too far. The Yogacara (Way of Yoga) school, also called Cittamatra (Mind Only), held that not everything was empty. The philosophers Asanga and Vasubandhu (ca. fourth century CE) held that since one experiences reality through perception, consciousness itself must have some form of inherent existence. Emptiness applies only to the objects of perception, not to the consciousness underlying perception. The resulting philosophy was a form of idealism that aimed at viewing the world as a projection of one's own consciousness.

During this period, Buddhist monastic institutions were repositories of knowledge and education. Buddhism in India declined in influence politically, losing ground to Hindu rivals, especially those of Shaiva sects. However, Buddhism expanded abroad into East and Southeast Asia. Kumarajiva (344–413), for example, brought Madhyamaka teachings of emptiness into China. In the fifth or sixth century, the legendary Bodhidharma introduced Ch'an (Zen) to China. Other missionaries introduced popular forms of Buddhist devotion in China as well as a pantheon of Buddhist divinities and the notion that all things are manifestations of a Cosmic Buddha. These developments spread popular forms of Buddhism as a devotional religion, amenable to prayer and worship of enlightened Buddhas and bodhisattvas. Conversely, Chinese pilgrims made their way into India. Most notable among these was Xuanzang (599–664), a pilgrim who visited Nalanda, the foremost Buddhist educational institution in India. He brought back to China numerous Buddhist texts and founded a school of Mind Only doctrine as well. As a result, when Buddhism virtually disappeared

from India in the twelfth century, East Asia became the foremost center of Mahayana Buddhist thought and activity.

The final division of Buddhism, originating in this period, is Vajrayana, the “Diamond Vehicle” or the “Thunderbolt Vehicle.” This is synonymous with Tantric Buddhism, a form that retains an adherence to the ideals and doctrines of Mahayana Buddhism despite holding practices and beliefs in common with Hindu forms of Tantra. Similarities between Buddhist and Shaiva Tantras include the reliance on secret initiations, the chanting of sacred mantra and meditation on *mandala*, and the identification with a divine being in meditation. Esoteric forms of Buddhism, like their Hindu analogues, first appear in the seventh century CE. By the tenth century CE, forms of Esoteric Buddhism made their way into Tibet, whose sects preserved these Esoteric traditions down to the present day.

Forms of Early Buddhism— Theravada and Others

Of the early sects of Buddhism, the sole surviving non-Mahayana tradition is that of the Theravada. The name “Theravada” is a Pali translation of the Sanskrit “Sthaviravada,” meaning the “School of the Elders,” and Theravada alone has maintained the use of the Pali language in its canon. Distinct ordination lineages as well as differences in philosophical interpretations (*abhidharma*) of the Buddha’s teachings distinguished this and other early sects.

Theravada represents a conservative tradition of Buddhism that historically maintained that the goal of Buddhism is one’s own *nibbana* (the Pali word for “nirvana”), the extinction of suffering, in contrast with the Mahayana ideal of

the bodhisattva. Moreover, unlike other traditions of Buddhism that view the Buddha as a cosmic or divine being who manifested in physical form to teach salvation, the Theravada sect maintained that the Buddha was merely a human being who found the way to nibbana and showed the way to others. Likewise, it has preserved a socially stratified and interdependent hierarchy between the monastic community (*sangha*) and the laity. In this relationship, monasteries are centers of education and spiritual direction but in turn rely on lay institutions for support. Theravada has also preserved the tradition that holds that junior monks are subordinate to senior monks, that all nuns are subordinate to all monks, and that the laity are subordinate to all monks.

As the sole surviving sect of early Buddhism, Theravada has preserved one of two extant collections of *Abhidharma*, the philosophical commentary on the Buddha’s teachings. This is due in part to the work of the fifth-century CE monk Buddhaghosa whose *Visuddhimagga* (*Path of Purification*) was a compendium of Theravada teachings. It incorporated much of the Theravadin *Abhidharma*, thus preserving it, and also included instructions on meditation, morality, and discipline, thus underscoring the importance attached to the reformation of the mind to achieve Buddhist awakening.

➤ BUDDHIST GENDER RELATIONS— NUNS IN THERAVADA

According to tradition, the Buddha ordained the first orders of nuns, although nuns were never equal in status to monks. Lists of rules for nuns were slightly more extensive than the 250 or so rules for monastic discipline and included the condition that even the most senior of nuns must remain subordinate to even the most junior monk. Orders of Buddhist nuns flourished in South Asia throughout the first millennium CE until the ordination lineage of Theravada nuns in Sri Lanka died out in the eleventh century. There have been recent attempts to revive orders of Theravadin nuns, however, through ordination lineages of nuns from East Asian Mahayana sects.

—Matthew Bingley

Theravada has historically held a strong following in Sri Lanka, where a monk named Mahinda introduced the sect in circa 250 BCE. Theravada enjoyed the patronage of the state throughout much of its history in this period and even down to the present. In this environment, Theravada thrived; indeed, the monk Buddhaghosa was originally from mainland India and settled in Sri Lanka. By the eighth and ninth centuries CE, Mahayana and Esoteric teachings supplemented Theravada orthodoxy in Sri Lanka until in the tenth century invasion from expanding Tamil kingdoms briefly disrupted the Buddhist Sangha in Sri Lanka. Theravada Buddhism reestablished itself as the state religion in the twelfth century, however, under the reign of Parakkama Bahu I (1153–1186). Theravada traditions also became established in Burma and other parts of Southeast Asia from the early centuries of the Common Era onward.

In northern and northwestern India, the Sarvastivada (“the view that all exists”) flourished in the early centuries of the first millennium. The Sarvastivadin *Abhidharma*, compiled in the third century CE, is the other of the two extant compilations of Buddhist philosophical commentary. What distinguished the Sarvastivadins was the view that all elements (*dharmas*) inherently exist in past, present, and future. One experiences change only because the mode of elements changes with time. This view proved to be controversial, and it helped give rise to other schools of thought. Nagarjuna, for example, in the third century CE criticized the idea of inherent existence with his philosophy of the radical emptiness of all things. The Sautrantika School was another sect that formed over doctrinal disagreements with the Sarvastivada.

The doctrines of the Sautrantika (“those who follow the sutras”) reflected a close adherence to the original teachings (sutra) of the Buddha. Figures such as the Buddhist logician Dinnaga (ca. fifth century CE) held that given the Buddhist belief in impermanence, it was fundamentally a mistake to view elements as existing forever. Instead, an element exists for only a moment and creates an effect as it ceases again. All of reality is continually blinking in and out of existence faster than one can perceive, but what

is experienced is the cumulative effect of momentary elements.

Another noteworthy early sect was the Pudgalavada (“the school of the person”), which held the controversial view that there was such a fundamental entity as a person (*pudgala*) who acted, followed the Buddhist path, and experienced nirvana. This person functioned much like a permanent soul, and the controversial nature of this doctrine can be readily seen given that a cardinal belief among all Buddhists is that there is no permanent or essential self. Despite the controversy that the Pudgala school generated, the Indian emperor Harsha (606–647 CE) patronized the Pudgala sect in the seventh century CE, at which time perhaps a quarter of all Buddhist monks followed this school.

With the sole exception of the Theravada in Sri Lanka and Burma and Esoteric Buddhism in Tibet, Buddhism virtually disappeared from South Asia by the twelfth century CE. There are a variety of reasons for this. One is that unlike in Sri Lanka, Buddhism lost royal patronage in favor of Hinduism throughout this period, with the exception of the Pala dynasty’s support for Buddhist institutions in northeastern India from 750 CE onward. Likewise, in the first millennium CE Hindu sects began to incorporate Buddhist ideas: Sankara’s Advaita Vedanta incorporated the non-duality of Madhyamaka, while Puranic literature described the Buddha as an incarnation of Vishnu, one sent to lead heretics astray. Finally, one cannot overlook the fact that Indian Buddhism lacked a martial tradition, unlike Hinduism, and Buddhism declined as Islam spread from central Asia into northern India beginning in the tenth century CE.

Tibet's Conversion to and Development of Buddhism

According to Tibetan religious tradition, Buddhist teachings first appeared in Tibet in the form of a box that fell from the sky onto the Yumbu Lhakang palace. Inside the box were a golden stupa and the bodhisattva Avalokitesvara's mantra written in gold. Although no one could read the small manuscript, the king enshrined and worshipped it, recognizing its sacred quality.

Tibet did not develop a writing system until the seventh century CE, and due to the scarcity of written texts it is difficult to write with certainty about early Tibetan religion. What is known is that by the early sixth century CE the kings of the Yarlung Valley had begun to build a military power capable of uniting the disparate and warring Tibetan regions. Tibet's neighbors—Nepal, China, India, and the nations of central Asia—were all Buddhist countries, and in the seventh century CE the Tibetan king Songtsen Gampo (ca. 609–650 CE) became the first Tibetan ruler to be converted to Buddhism.

Tibetan histories credit Songtsen Gampo's conversion to two of his wives, the Nepali princess Bhrikuti and the Chinese princess Wen-cheng. Both of these women were devout Buddhists, and Tibet's first Buddhist temples, the Jokhang and Ramoche, were built to house the Buddha images that these wives brought with them to Tibet. Songtsen Gampo sent Thonmi Sambhota to India to develop a script for writing the Tibetan language so that Buddhist texts could be translated into Tibetan. Western scholars speculate that part of Songtsen Gampo's interest in Buddhism may have stemmed from his political aspirations. While Tibet was still a relatively isolated collection of warring principalities, its local rulers had no need for external recognition of their sovereignty. Songtsen Gampo's emerging dynasty, however, had international ambitions, and affiliation with Buddhism, the religious lingua franca of the time, granted the Tibetan king widespread cultural legitimacy.

The second of Tibet's great Dharma kings was Trisong Detsen (ca. 740–798 CE). Trisong Detsen is remembered for inviting the Indian monk San-

Jokhang, the Buddhist temple built by Songtsen Gampo in the seventh century CE. (Jack Versloot)

taraksita to Tibet, where he ordained the first Tibetan monks. With the help of the tantric master Padmasambhava they established Samye, Tibet's first monastery. A fervent Buddhist, Trisong Detsen decreed all of Tibet a Buddhist nation and appointed aristocratic landholding families the task of providing for the material needs (mainly food and robes) of the new Buddhist monks. Through the middle of the eighth century Tibet looked to both India and China for instruction in Buddhism. Tension slowly developed, however, between the Chinese monks and their supporters and the Indian teachers and their followers. Traditional accounts state that in 755 CE a great debate was held at Samye Monastery to decide the future of Buddhism in Tibet. The Indian faction won the debate, and from then on Tibetans followed only the Buddhist traditions from India.

During these first centuries of Buddhism's establishment in Tibet, the new religion remained largely the purview of the royal court and certain aristocratic families. Much of the common Tibetan populace remained ignorant of the new religion, and even some aristocrats, inimical to anything foreign and determined to maintain the status quo, continued leading their religious lives much as they had before Buddhism's arrival. The pre-Buddhist practices are often referred to as Bon, and they included rituals for calling the soul of the recently deceased to guide it on its way, offerings to mountain gods, ransom rituals that depended upon animal

THE SAMYE DEBATE

The Samye debate ranks as one of the most important events in the history of Buddhism in Tibet. Buddhist histories depict it as a formal competition initiated by King Trisong Detsen in order to determine whether Tibet would adopt the Chinese Chan Buddhist tradition of sudden enlightenment or the Indian Buddhist tradition of a gradual path to liberation. Traditional accounts describe the Indian monk and scholar Kamalasila winning a decisive victory for his supporters against the Chinese meditation master Hashang Mahayana. Hashang, his disciples, and all Chinese Buddhists were then banished from the country, and all further translations of Buddhist scriptures were rendered solely from Indian texts.

Contemporary scholars, however, suspect that the Samye debate was not a one-time contest of reasoning but a protracted period of rivalry. Unconvinced that the outcome was decided solely on the basis of which tradition represented the most authentic and effective religious path, scholars suggest that due to mounting political tension with Tang China the Tibetan court decided in favor of the Indian faction in order to limit the growing Chinese influence in the country. In fact, eighth-century Tibetan contacts with China were more developed than those with India. One of the earliest extant Tibetan historical narratives, the *dBa' bzhed*, emphasizes the important role that Chinese monks and Chinese teachings played in Tibet's conversion to Buddhism, and scholars believe that Chinese Buddhist influence was not summarily ended as a result of the royal dynasty's decision to sponsor the adoption of the Indian Buddhist system.

—Alyson Prude

sacrifice for curing illness, the creation of demon-catching traps, and various forms of divination. Storytellers and bards roamed the country reciting the origin legends of the first kings, a practice believed to uphold and protect the kingdom. The voices of local guardian deities spoke through the bodies of spirit mediums, giving instructions for their worship and diagnosing the causes of accidents and misfortune.

Buddhism continued as the official state religion through the reign of King Relpachen (ca.

806–840 CE). Many Buddhist texts were translated from Sanskrit, Tibetans traveled to India to bring back Buddhist texts and teachings, and Indian masters were invited to the royal court.

Relpachen's assassination and his younger brother Lang Darma's seizure of the throne marked a shift in the royal court's propagation of Buddhism. The reign of Lang Darma is described in Buddhist histories as a time of persecution, and Lang Darma is portrayed as an evil king intent on eradicating Buddhism and restoring the practices of Bon. Contemporary scholars offer a slightly different account. Evidence points to the successive occurrence of numerous natural disasters, including frosts, hailstorms, crop disease, famine, and epidemics as influencing Lang Darma to return to some of the indigenous rituals that had protected the land and its inhabitants for so many years before the adoption of Buddhism. Lang Darma was supported in these efforts by those elite families who had remained averse to foreign influence and the new religion. The previous kings' ardent support of Buddhist monasticism had strained the financial resources of the state. According to contemporary scholars, Lang Darma merely withdrew state financial support from Buddhist monks and monasteries. He did not actively suppress Buddhism in the way that Buddhist kings, such as Trisong Detsen, had persecuted Bon by throwing Bon texts into rivers or sealing them inside Samye's black stupa.

Lang Darma's assassination by a Buddhist monk in 842 initiated a time of political and social chaos in Tibet and marked the end of the unified Tibetan empire. Monks fled to the northeastern borders of the country, and monasticism disappeared from central Tibet. During the next 150 years Buddhism went underground and was practiced, often in secret, by village tantrics and married householders. Buddhist practices during this time were employed mainly for conducting funerary rituals, blessing crops, and soliciting protection from evil spirits.

The second dissemination of Buddhism in Tibet is dated to 978 CE when Yeshe O, the king of the western Tibetan regions of Guge and Purang, again began sending Tibetans to India to bring back teachings and inviting Indian Buddhist scholars to Tibet. Yeshe O was concerned

about the legitimacy of the tantric rituals that Tibetans had been practicing during the preceding period of turmoil and sought to ensure that all new translations were authentic and correct. The earlier texts and practices were heavily criticized by the proponents of the new Buddhist schools, but their practitioners, who came to be identified as the Old Translation School (known in Tibetan as the Nyingma), held their ground.

Bhakti in South India

It is around the seventh century CE, roughly at about the same time that Muhammad was proclaiming Islam as the true faith in the desert oases of Arabia, that *bhakti*, as a codified movement, emerged within Hinduism. Bhakti began in the lands where the Tamil language was spoken and in a few centuries spread over all the regions of India. The term “bhakti” comes from the Sanskrit root *bhaj* (“to evoke,” “to sing praise of”). It is a name given to a form of faith in which the devotee is intensely and individually involved with the personified deity he or she worships. There is urgency in the appeal, a passionate relationship with the divine form that is experienced and then sung through ecstatic lyrics by the saint poets. These songs were sung in melodies called *pans*, and modern musicians are trying to revive these precursors of modern-day ragas of classical Carnatic (southern Indian) music. The Tamil bhakti was a romantic movement, not intellectual or abstract as the devotion expressed in the famous Sanskrit holy book the Bhagavad Gita (ca. second century CE).

➤ BHAKTI AS A WOMAN

In one of the ancient Sanskrit texts called the Bhagavatamahatmyam, *bhakti* is personified as a woman, and she says, “I was born in Dravida grew up in Karnataka and became old in Maharashtra and Gujarat.” She must have been even older when she reached Bengal. Thus, *bhakti* is a Pan-Indian movement but had its birth in Dravida, which is South India.

In this hymn to the dancing Siva of the temple of Tiruvalankatu, Karaikkal Ammaiyar begins by a self-description, calling herself the “female ghoul,” and concludes the stanza with the Lord Siva dancing in the deathly arena.

“With emaciated breasts and protruding veins,
With hollow eyes and toothless gums
With a belly sunk concave and mousy hair on the crown
With molars like fangs
With bony knees clattering
Does live this lamenting female ghoul
This burning ground, wherein she dwells
It is here my Father chooses to dance
His whirling tresses fanning the eight directions
My Father, who lives in Tiruvalankatu
Cools my body with his Grace.”

—Rajeshwari Ghose

Hymns on Tiruvalankatu, Hymn 1, Verse 2. Translated by Rajeshwari Ghose.

The Tamil bhakti poets sing praises of specific manifestation of the god in a particular temple and or in a particular sacred spot. Thus, pilgrimage to the holy shrines and visual descriptions of the icon are intrinsic parts of this movement. In going on pilgrimage, they also created a notion of sacred geography within the Tamil lands, thereby adding local spots watered by the holy river Kaveri to the Pan-Indian sacred landscape. The bhakti saints also place an enormous value on being loyal and respectful to the community of believers, called *bhaktas*. Thus, there is the feeling of belonging to a collective, and this collective was energetically evangelizing its faith.

The bhakti hymns were chiefly addressed to two forms of the Divine, Vishnu and Siva. Those

who composed hymns in praise of Vishnu were called the Alvars, and there were 12 important Alvars who are respected as saints by the worshippers of Vishnu. There were 63 saints who are venerated as the founding fathers of the bhakti movement dedicated to the god Siva. These 63 were collectively called Nayanmar (plural of Nayanar). Images of the Alvars and Nayanmar are worshipped in the temples of southern India. Though all the hymns are characterized by a very personal note and by an intimate approach to a personified form of the divine, there are vast differences between the composition of one saint and another, and generally there is a marked difference between the approaches adopted by the Vaishnavas (worshippers of Vishnu) and the Saivas (worshippers of Siva).

Among the compositions of the Nayanmar or the Saiva poet saints we can clearly discern three paths leading to the divine. The first is to approach god as father, the second is to hail him as master, and the third is to treat god as an intimate friend. The three most famous Nayanmar are Appar, Sambandhar, and Sundarar, and later interpreters of bhakti attribute the three paths, respectively, to this sacred trio. There is only one female Nayanmar. She is reverentially referred to as the Mother of Karaikkal, Karaikkal being the name of the city she came from. Among the Alvars too there is only one woman saint poet. Her name is Kothai, and she is popularly called Andal or the Ruler, referring to her power over her lord, the god Vishnu. The way these two women approach the divine and the way they led their lives show the wide divergence that exists within the bhakti literature and also provides us interesting information on the notion of gender in the Hindu devotional universe.

Gender has been understood and interpreted in many different ways in the vastly disparate traditions of Hinduism. With no central ecclesiastic authority and with literature and material artifacts of over 3,000 years, we are actually looking at a massive labyrinth of myths, rituals, poetry, and visual representations that can inform us on how gender was constituted within the conceptual framework of the Divine.

Kodai or Andal falls in love with Vishnu. In one of her poems she addresses her divine lover and says, “My beautiful lover, you have put clay

around me and poured molten metal into my heart.” Here the metaphor centers on the making of images of the gods and goddesses by the lost wax method. Her heart, says Andal, has melted with love, and all that remains is the clay of her mortal body. While Andal speaks of her passionate love for her divine lover, there are men saints of the Vaishnava tradition who speak, adopting the voice and persona of the female, longing for union with the male god. Adoption of the female voice to invoke God as the lover is also known in Christian tradition, but it is less frequently used than in the Hindu bhakti tradition. Sometimes the deity to whom the hymns are addressed crosses the boundaries of gender. One of the Alvars called Nammalvar sings to the male god Vishnu:

“Being my father
My friend and the mother
Who gave birth to me.”

Thus, the bhakti tradition seems to operate in two levels, namely, that of the abstract god and that of the devotee so consumed by love of god that he is no longer aware of his gender and becomes the lovelorn maiden.

Our other example of a female bhakti poet devoted to Siva is that of Karaikkal Ammaiyar. While Andal, the Alvar referred to above, is believed to have lived in the ninth century, Karaikkal Ammaiyar is placed much earlier in the late sixth century or thereabouts. While Andal was a beautiful woman who got sensuously dressed to please her lord and who adorned herself with the garland meant to decorate the image of the lord, Karaikkal Ammaiyar prays to the god Siva to divest her of her youth and beauty, which she sees as a distraction both to herself and those who gaze at her physical beauty. She wants to look withered, old, and ugly, and her image of her god is of one who dances the dance of death in the cemeteries and presides over the cruel realities of death, war, and suffering. It is an image in stark contrast to that of the world of the bride Andal passionately dreaming of the lover’s embrace and of all things lyrical and beautiful.

Karaikkal Ammaiyar chooses to sing of the god in the temple town of Tiruvalankatu. Her images of herself and her god are couched in terms

that make the macabre and the terrible beautiful. The message is that one, pointed devotion to the god Siva will conquer all fear of death. The cemetery (cremation ground, for the corpse was cremated in the Hindu practice) is simply a metaphor for death and all the destructive forces that are within us. She finally reaches Mount Kailasha, the abode of the god Siva, who hails her as “Mother.” Thus, while Andal, meaning the ruler, wins over the heart of her lord by her passionate sensuous longings, Karaikkal Ammaiyar by her strange images and lifestyle placed outside the normal codes of behavior, earns the respectful epithet of “Mother” from Siva, her god.

The Tamil bhakti poets accepted all the myths and belief systems of the Sanskrit religious works but gave them expression through the local Tamil language, thereby giving access to many more people. Sanskrit was like Latin in the medieval ages in Europe, an ecclesiastic language for the learned clergy. By using Tamil and by talking to God in endearing Tamil and by referring to god as a Tamilian, they localized the Pan-Indian faith and gave it a new stimulus.

Confucianism, Buddhism, and Daoism—Transformation of Chinese Religion

By 300 CE, China was no longer under unified rule. The fortunes of the most prominent indigenous religious tradition, Confucianism, had fallen with the Han dynasty (202 BCE–220 CE), while those of its lesser-known native and foreign counterparts, Daoism and Buddhism, were rising steadily. These three transformations in-

fluenced the subsequent development of Chinese religious history throughout the first millennium CE and beyond. From the period of disunity (220–589 CE) onward, Chinese religion would be defined by the interactions among Confucianism, Buddhism, and Daoism.

During the Han, the term “Daoism” (*daojia*) denoted a mélange of legal, medical, philosophical, and occult lore. Later it signified a constellation of sectarian movements, each claiming a host of divinely revealed writings as authoritative scripture alongside well-established texts such as the *Laozi* (*Daodejing*) and the *Zhuangzi*. These movements’ healing and longevity practices and commitment to moral rectitude no doubt made them doubly attractive to those searching for meaning in the fragmented post-Han world. Led by Zhang Ling (later known as Zhang Daoling), the Celestial Masters (Tianshi) venerated Laozi as a god and required rituals of confession for its members in anticipation of the imminent end of the world. Celestial Masters, whose title signified initiation into an unseen cosmic bureaucracy, devoutly expected to assume positions of power in a purified society ruled by the elect. Daoist theocracies ruled by groups such as the Celestial Masters and the Yellow Turbans (*huangjin*) briefly flourished here and there. At the personal level, techniques for attaining physical immortality were in vogue, especially among the gentry of the south to which Chinese regimes had retreated in the wake of northern barbarian invasions.

By the fourth century CE, Buddhism had developed from a hitherto little-known South Asian faith introduced by merchants and missionaries traveling the Silk Roads trade routes into a growing tradition patronized by Chinese elites. Initially it did not appear likely that Buddhism would take root in China. Although trade routes had linked China to other regions of Eurasia for centuries, travel was always difficult and dangerous, especially across the Himalayas to the south and the great deserts to the west. The scriptural languages of Buddhism, such as Pali and Sanskrit, are completely unrelated to Chinese, and thus the translation of foreign texts and concepts into the vernacular presented an enormous challenge. Perhaps the most formidable obstacle to Buddhism in China was the uniformly nativist

Two statues of the bodhisattva Guanyin. In Buddhism, a bodhisattva is an enlightened being who defers release from rebirth in order to assist other suffering beings. The statue on the left was produced during the first half of the seventh century CE and reflects the androgynous qualities of Central Asian Buddhist iconography, while the figurine on the right dates to the Yuan dynasty (1271–1368 CE) and illustrates the feminization of this figure in Chinese Buddhist art. (Réunion des Musées Nationaux/Art Resource, NY/Asian Art & Archaeology/Corbis)

and negative Confucian reaction that it provoked. But in the absence of state support, Confucianism was at a profound disadvantage and was unable to mount any effective resistance to Buddhist proselytization efforts.

Daoist movements were in nascent stages of development and could not compete with the better-organized Buddhist missions. Many Daoists as well as some disillusioned Confucians were attracted to the apparent similarity of Buddhist teachings with those familiar to them from texts such as the *Laozi* (*Daodejing*) and the *Zhuangzi* and movements such as the Dark Learning (*xu-anxue*) school. This attraction was encouraged by early translators of Buddhist texts into Chinese, many of whom adopted Daoist terminology in order to express Buddhist concepts. Later sectarian Daoist movements, such as the Highest Clarity (Shangqing) and Spiritual Treasure (Lingbao) sects, borrowed other Buddhist ideas (such as the doctrine of karmic retribution), resulting in further Buddhist-Daoist syncretism.

By the end of the long interregnum between unifying dynasties, Buddhism's prestige

had reached its zenith. Yang Jian, the general who reunified the empire and reigned as Emperor Wendi of the short-lived Sui dynasty (581–618 CE), assumed the mantle of a Buddhist *chakravartin-rajā* (“wheel-turning king,” i.e., universal monarch) in order to legitimize his rule. Under the succeeding Tang dynasty (618–906 CE), Chinese Buddhists and their elite patrons sponsored missions to the regions now known as Vietnam, Korea, and Japan, and Buddhist diplomacy helped to cement cultural and political links between East Asian courts. Chinese sensibilities also transformed Buddhist iconography, as the bodhisattva *Avalokitesvara* (masculine in South and central Asian representations) became Guanyin, a highly feminine figure in Tang art. Tang trade links to central, South, and West Asia enabled the transmission of still more foreign religions to China, including Islam, Judaism, Manichaeism, and Nestorian Christianity. Although none of these ever attained the popularity enjoyed by Buddhism, sizable communities affiliated with each tradition thrived throughout the Medieval Period, and large Muslim communities still exist in China today. While elites in each religious tradition maintained the ideals of exclusivity and orthodoxy, there is no evidence that average Chinese showed much concern for exclusive religious participation or pure doctrinal teachings. Instead syncretism prevailed, and each of the Three Teachings, or *sanjiao* (Buddhism, Confucianism, and Daoism), was enveloped in the trappings of Chinese popular religion, with its myriad local cults, deities, and mythologies.

Both the Sui and the Tang patronized Confucianism (in addition to Buddhism), reestablishing its canon as the basis for civil service examinations. Confucian ethics, with its three bonds of obedience (ministers to rulers, sons to fathers, and wives to husbands), continued to define social relationships among the educated. Confucian ritual dominated all ceremonies of public life and influenced religious practices among families and extended communities such as villages. Near the end of the Tang, Confucian and Daoist cliques at court persuaded Emperor Wuzong (r. 841–846 CE) to launch a fierce persecution, directed at “foreign” religions, destroying Buddhist institutions, confiscating Buddhist property, and secularizing monks and nuns

throughout his realm. This disaster prompted Chinese Buddhists to view their era as the last days of the dharma (*mofa*), a degenerate period in which customary methods of transmitting the Buddha's teachings would not suffice. Subsequently, new Chinese Buddhist sects developed around reliance upon a single practice, such as meditation (in Chinese, *chan*, in Japanese, *Zen*) or the recitation of a particular *sutra*, thought to be uniquely useful for gaining salvation in such troubled times. These developments in China strongly influenced Buddhist movements throughout East Asia.

After the fall of the Tang, various warlords competed for supremacy until a former Tang commander, Zhao Kuangyin, restored imperial unity as Emperor Taizu (r. 960–976 CE) of the Song dynasty. Having relied upon Confucian scholars to help stabilize and legitimize their regime, early Song emperors gratefully embraced Confucianism and continued the anti-Buddhist policies of the late Tang. Some endorsed Daoism, leading to the imperial compilation of the Daoist scriptural canon in 1019 CE. Nonetheless, while the influence of Confucianism only grew stronger under Song rule, Buddhism and Daoism retained their permanent places as fixtures in the Chinese religious landscape. The patterns of interaction between these three traditions set in motion during the Period of Disunity and the political precedents established by the succeeding dynasties ensured that Chinese religion would continue to be defined by syncretism, state control, and struggles for supremacy.

Early Japanese Buddhism

The impact of Buddhism on Japan's political, religious, and artistic development is impossible to exaggerate. Today, some 14 centuries after Buddhism reached its shores, Japan remains one of the world's great centers of Buddhist practice and art and a major wellspring for the ongoing migration of Buddhist traditions to the West.

Originating in India around 500 BCE, Buddhism swept across Asia in just 1,000 years. It came last to Japan, crossing the sea in the mid-sixth century. It spread fast under the patronage of regent Shotoku Taishi (547–622), the nephew of Empress Suiko. Shotoku embraced the new faith (he was one of its first converts). He fostered its acceptance as both a superior religious philosophy and a powerful political tool for creating strong centralized governance under the emperor's guidance. Shotoku is credited with constructing numerous temples, centralizing state administration, importing Chinese bureaucracy, and enacting a 17-article constitution that established Buddhist ethics and Confucian ideals as the moral foundations of the young Japanese nation. During his regency, many missions were dispatched to China. Prince Shotoku never became a monk, but in modern popular belief he is revered as a Buddhist saint.

The Korean and Chinese missionaries who introduced Buddhism to Japan brought rituals and texts from both the Theravada and Mahayana schools, but the Mahayana form in particular struck a chord with its promise of salvation to both monastic followers and laity alike. The early missionaries also brought their art and techniques for reproducing Buddhist icons and sutras. Three texts were of great influence in Japan: the Lotus Sutra, the Sutra of Golden Light, and the Benevolent Kings Sutra. These were called the Three Scriptures Protecting the State. Indeed, the Japanese court's early support for Buddhism was based largely on the court's desire to use Buddhism as an instrument of state power and consolidation rather than an instrument of salvation for the masses. Buddhist ceremonies at the time were organized predominantly for the court to ensure the welfare of the country, to expel demons of disease, and to ensure rain and thus abundant harvests.

➤ KOBO DAISHI—ONE OF JAPAN'S MOST BELOVED BUDDHIST SAINTS

Kukai (Kobo Daishi) was the patriarch of the Shingon sect of Esoteric Buddhism. Shingon is Japan's version of Vajrayana (Tantric) Buddhism. Together with Hinayana and Mahayana, Vajrayana represents one of the three basic forms of Buddhism in Asia today. It is especially strong in Japan and Tibet and is intricately connected with the mandala art form. Shingon's most prominent deity is Dainichi Buddha, whose symbol is the vajra (thus Vajrayana, the Sanskrit term for "Diamond Vehicle").

Posthumously named Kobo Daishi (the Great Teacher), Kukai remains one of Japan's most beloved Buddhist saviors. Folklore says that he attained Buddhahood before death. Portraits of him abound. The Japanese today tend to ignore doctrinal differences when honoring him. Kukai traveled to China in 804 and was initiated in esoteric teachings by the Chinese priest Huiguo. Kukai returned in 806, and by 816 he obtained imperial sanction to construct his monastery on Mount Koya, a serene location on the Kii Peninsula still considered a holy land and one of modern Japan's most popular pilgrimage sites.

Kukai played an active role in many fields, performing rituals for the emperor, constructing a large reservoir in Shikoku for the common people, and establishing the first school for common citizens. His legend is riddled with folklore. He is

Tocho-ji Temple in Fukuoka, Japan, was founded by the scholar-priest Kobo Daishi in 806 CE. (Vanni/Art Resource, NY)

credited with everything from inventing Japan's kana script to introducing homosexuality. He is one of Japan's most celebrated calligraphers and supposedly published Japan's first dictionary. He became a major patron of the arts and reportedly founded hundreds of temples across Japan. The Shikoku Pilgrimage to 88 Sites is a popular pilgrimage attributed to Kukai. Most devotees carry a staff bearing the words "we two walk together."

—Mark Schumacher

Buddhism quickly became the state creed. By the eighth century, Emperor Shomu (d. 756) ordered the establishment of a nationwide system of provincial temples. This fast transition, however, was not always peaceful. In Prince Shotoku's time, it had sparked a war between the pro-Shinto faction (Mononobe clan) and pro-Buddhist forces (Soga clan). Buddhism won the day, but its subsequent success owed much to its tolerance and absorption of the older deities of the indigenous Shinto mountain cults. Before Buddhism, Shinto shamanism and mountain worship were the predominant forms of native faith. Japan's pre-Buddhist beliefs in nature spirits and holy men with magical powers were incorporated into Buddhism during the Nara (645–794) and Heian (794–1185) periods, resulting in a complex blend of Shinto-Buddhist practice.

One of the most celebrated mountain sages was En no Gyoja. This legendary holy man was a mountain ascetic (*yamabushi*) of the late seventh century. Like much about Shinto-Buddhist syncretism, his legend is riddled with folklore. He was a diviner at Mount Katsuragi on the border between Nara and Osaka. Said to possess magical powers, he was expelled in 699 to Izu Prefecture for allegedly misleading the people and ignoring state restrictions on preaching among commoners. He is considered the father of Shugendo, a major syncretic movement that combined pre-Buddhist mountain worship with Buddhist teachings. Popular lore says that he climbed and consecrated numerous sacred mountains.

By the ninth century, Buddhist temples were constructed alongside Shinto shrines on many sacred mountains, epitomized by the

powerful Tendai temple-shrine multiplex on Mount Hiei (Shiga Prefecture) and by the holy places throughout the Kumano mountain range. The native Shinto *kami* (deities) residing on these peaks were considered manifestations of Buddhist divinities, and pilgrimages to these sites were believed to bring double favor from both their Shinto and Buddhist counterparts. Another major center of syncretism was the Kasuga shrine complex in Nara. The number of deities proliferated. Despite earlier resistance, syncretism was relatively smooth and marked by religious tolerance.

Shinto-Buddhist syncretism was actually formalized and pursued based on a theory called Honji Suijaku, with Shinto gods recognized as manifestations (*suijaku*) of the original Buddhist divinities (*honji*). In the later Kamakura period some Shinto sects proposed the opposite, proclaiming the Shinto gods as honji and Buddhist deities as *suijaku*.

Scholars typically divide the Nara and Heian periods into two categories. The so-called Six Schools of Nara (the Sanron, Hosso, Kegon, Ritsu, Jojitsu, and Kusha sects) were mostly academic schools under state control that were centered in Nara and were devoted to mastering Buddhist philosophy from China and to maintaining court patronage. This period is called Nara Buddhism. It was marked by strong court-clergy relations and by lavish state spending on Buddhist temples, images, and texts. It did not show much doctrinal innovation and was largely devoted to state functions. In contrast, the Heian era is considered a groundbreaking period. Called Heian Buddhism, it centered around the establishment of two new schools, Tendai and Shingon, that both played key roles in the Shinto-Buddhist merger. The two founded their monasteries in mountain retreats away from the capital, thus gaining greater autonomy from the court. Both emphasized meditative practices and taught that everyone, not just the elite, had the potential to realize Buddhahood.

Priest Saicho (767–822) founded Japan's Tendai sect, and Priest Kukai (774–835) founded the esoteric Shingon sect. Both schools originated in China, where Saicho and Kukai had traveled to study the teachings. Once transplanted to Japanese soil, both schools flowered with innovation. Saicho's sect attempted a synthesis of

various Buddhist doctrines, including faith in the Lotus Sutra, esoteric rituals, Amida (Pure Land) worship, and Zen concepts. Tendai gained great court favor, rising to eminence in the late Heian era. Shingon, in contrast, was predominantly esoteric. Its doctrines were mystical and occult and required a high level of austerity. Elaborate and secret rituals (utilizing mantras, mudras, and mandalas) were developed to help practitioners achieve enlightenment. Despite its complex practices, Shingon exerted a profound impact on religious art and the faith of the court and monastic orders.

Religious pilgrimages were instituted during the mid-Heian era as well, often by priests who had made the arduous sea journey to China, including Saicho, Kukai, Ennin (794–864), and Enchin (814–891). Pilgrimages became a lasting practice thereafter. At the same time, Lotus Sutra Meetings (*bokke-e*) became popular among the nobility. By the late tenth century, meetings were designed for the salvation of the lower classes. Shinto shrines joined in, adding to the syncretic Shinto-Buddhism of the day. Gatherings for the working class were particularly common in the Kumano region.

Heian Buddhism and Shinto-Buddhist syncretism helped lay the foundation for the widespread propagation of Buddhism among the masses in the Kamakura Era.

Korean Buddhism, 400–1000 CE

For nearly a millennium, from its arrival around 400 CE until well into the Koryo era (918–1392), Buddhism played a dominant role in the political, social, and cultural life of the Korean peninsula. During this period Buddhism overshadowed

WONHYO

Wonhyo (617–686) was a man of Silla and one of the most prominent figures in the history of Korean Buddhism. Legend states that on the night he was conceived his mother dreamt that a shooting star had entered her womb and that his birth was heralded by multicolored clouds hovering over the earth. Silla had officially adopted Buddhism a century before Wonhyo's birth, and in his boyhood Wonhyo opted to enter the Buddhist priesthood. Unlike many of his contemporary monks, Wonhyo never made the journey to China to study Buddhism, although he attempted to on more than one occasion. One well-known story concerning Wonhyo relates how en route to China he took shelter in a cave in western Korea. Waking thirstily in the night, he groped in the dark until he found what he thought was a gourd. He was immediately refreshed by the pure water he found within it. In the morning Wonhyo discovered he had been sleeping in a tomb, and the gourd was in fact a human skull containing putrid water. From this experience Wonhyo received the revelation that all reality was a creation of consciousness. During Wonhyo's adult years the Unified Silla kingdom suffered from an excess of Buddhist teachings, resulting in doctrinal strife and disunity. Wonhyo set out to harmonize the various Buddhist doctrines that had been imported into Korea over the past century and in so doing became perhaps the greatest contributor to a distinctly Korean style of Buddhism. His massive efforts to unify the plethora of Buddhist scriptures into a unified doctrine proved highly influential in China and Japan as well. Upon his passing Wonhyo was granted the posthumous title "National Preceptor Who Harmonizes Disputes."

Confucianism as the guiding state ethos and was a primary focus of intellectual and artistic energies.

By most accounts, Buddhism first arrived on the Korean peninsula through a proselytizing Buddhist monk of the Chinese Eastern Qin kingdom, who brought the new religion to Koguryo in the late fourth century. Shortly thereafter, the more southerly Korean kingdom of Paekche adopted the faith. The kingdom of Silla farthest south was certainly exposed to Buddhism from around 400 CE. But in a situation closely analogous with Japan, Buddhism seems to have been first greeted by Silla with animosity and distrust. The Silla aristocracy in particular perceived in the foreign religion a threat to their privileges, founded in part upon their close association with the worship of native shamanistic deities. But one secret of Buddhism's success worldwide has been its ability to accommodate native beliefs. Silla officially adopted Buddhism in 527 after, legend states, the Buddhist official Ich'adon was martyred and his blood flowed the color of milk. The Silla aristocracy soon found grounds of accommodation with the new faith, while the Silla monarchy would also use it to bolster royal authority.

Although the Hinayana school of Buddhism, with its stress on individual meditation and salvation, was tolerated, it was the Mahayana school, with its vast hierarchy of bodhisattvas, emphasis on prayer over meditation, and appeal to the masses, that prevailed in Three Kingdoms Korea. For one thing, the hierarchical nature of Mahayana Buddhism conformed well to social realities on the Korean peninsula. Similarly, the Mahayana concept of bodhisattvas—lesser Buddhas who had forsaken final enlightenment to aid humans in their everyday struggles—readily accommodated many native deities.

When Buddhism arrived on the peninsula the Three Kingdoms were in the process of centralization and mutual rivalry. It was perhaps natural then that the monarchies of those kingdoms took the lead in the acceptance and promotion of the faith. Silla in particular linked Buddhism with royal power and the protection of the homeland. For a century or so after the faith's adoption in Silla, monarchs of that kingdom took on Buddhist names and styled themselves as Buddhist kings and Silla in particular as

a Buddhist Land, specially chosen to take the lead in the promotion of the doctrine. In the Silla capital of Kyōngju the massive Hwangnyong Temple symbolized Silla's own vision of itself as Buddhist Land. The youthful bands of male Hwarang, who gained their greatest glory during the battles for unification, became linked to the worship of the Maitreya Buddha. In short, Silla's promotion of Buddhism was intimately tied to the growth of royal power and the drive for peninsula hegemony.

With the aim of promoting Buddhism on the peninsula, many monks from the Three Kingdoms and later Unified Silla made the pilgrimage to China and even India in search of Buddhist sutras and personal enlightenment. The Silla monk Hye'cho (704-787), for instance, recorded his long journey to the birthplace of Buddha in India in a five-volume travelogue (which was presumed lost until its rediscovery in a Buddhist grotto in Dunhuang, China, in 1908). Likewise renowned was the Paekche monk Kyōmik, who voyaged to India and returned safely to Paekche in 526, carrying vast amounts of Buddhist sutras that were eventually translated into Chinese (then being used by the Korean kingdoms). It is a testament to the efforts of such pilgrimages that the Silla monk Wonhyo in the seventh century was able to assimilate and harmonize the bewildering array of Buddhist doctrine without ever having left Korea.

In 668 Silla, with help from Tang China, finally succeeded in defeating its rivals and unifying the peninsula. Although relations with Tang were initially troublesome, with Tang wishing to carve its own colonies out of the defeated kingdoms, Silla eventually prevailed. Following Silla's absorption of the Buddhist legacies of Paekche and Koguryo and then the normalization of Silla-Tang relations around 700, Korean Buddhism was prepared to enter a more intellectually mature period.

For Buddhism in Korea, Unified Silla was a period of unparalleled intellectual vigor and development. Foremost among the Buddhist figures of the period were the contemporaries Ŭisang (625-702) and Wonhyo (617-698). Ŭisang studied in Tang China and returned to Silla to found the Korean Hwaōm (Huayen, Kegon) school, one of the major sects of Silla Buddhism.

By the time of Silla unification, so many various Buddhist sutras and doctrines had entered Korea that what emerged was a crisis mirroring the confusion of Buddhist doctrine then prevalent in China. The overall result was a Buddhism whose ultimate meaning was lost in the cacophony of various teachings. While Wonhyo never benefited from study abroad, his intellectual efforts are credited with bringing the various Buddhist doctrines under a unifying system of thought.

Ironies aside, the material splendor of Korean Buddhism is one of its most striking aspects, especially in the case of Silla. The Silla capital of Kyōngju (its present-day name) remains a vast storehouse of Silla period Buddhist temples, pagodas, murals, statues, and stupas. Most impressive is perhaps the stone Buddhist grotto of Sōkkuram, just outside the Silla capital. Echoing similar Buddhist grottos in northwestern and western China, Silla's Sōkkuram ("stone cave hermitage") is a masterpiece of Silla craftsmanship and a testament to the deep inroads that the faith had made by the eighth century.

The socially turbulent period of Late Silla saw a new development in Korean Buddhism with the growth in popularity of Sōn (Chan or Zen) thought. Although this meditative sect of Buddhism had arrived from China as early as the seventh century, it failed to make an impact until the early ninth century. Its rise in popularity has been linked to the social realities of late Unified Silla, namely the rise in power of local gentry at the expense of capital aristocracy. The powerful local gentry of late Unified Silla, including Wang Kōn, the future first king of Koryō, became the primary supporters of Sōn Buddhism. But its appeal may also be attributed to its dismissal of textual learning for personal meditation and sudden enlightenment. Over the century bridging late Unified Silla and early Koryō a total of nine independent Sōn monasteries were established on nine different Korean mountains, each headed by a patriarch. Unlike the earlier urban-centered Buddhist temples, Sōn temples chose as their locale isolated mountain retreats. In time Sōn overtook the textual schools of Korean Buddhism to become the main current of Buddhism in the Koryō period.

Following the fall of Silla in 927, Buddhism, notably Sōn, continued to play key social and

cultural roles during the succeeding Koryŏ dynasty, although it would slowly be eclipsed by Chinese-inspired Confucian statecraft in the realm of politics.

Shankara and the Reformation of Hinduism

Shankara (788–820 CE), also known as Shankaracharya and Adi Shankaracharya, may be the best known of classical Hindu philosophers. He developed the philosophy of Advaita Vedanta and established the Dashanami order of Hindu monks. His reforms helped give Hinduism the basic structure that it has, right to the present day. When, in the nineteenth century, modern Hindu thinkers sought to reform their tradition, the work of Shankara provided their chief model and inspiration.

Hinduism, in Shankara's time, was divided into numerous sectarian groups and was greatly weakened by the philosophical critiques and widespread popularity of anti-Vedic traditions, particularly Buddhism but also Jainism. Shankara recognized the validity of many of the Buddhist critiques of Brahmanical thought but also affirmed the truth of the Vedic revelation as a *pramana*, or basis for discerning the true nature of reality. He saw a deeper unity underlying the various Hindu traditions and taught that the deities at the basis of these traditions were all, ultimately, manifestations of one supreme divine reality. Finally, he organized a set of monastic in-

stitutions to perpetuate his vision, ensuring that it did not die with him.

A child prodigy, it is said that Shankara was defeating prominent philosophers in public debate at a very young age, mastering the four Vedas by the age of eight. He was drawn early to the life of a *sannyasin*, or wandering monk. Born in the southern state of Kerala, he traveled north where he met his guru, Govinda Bhagavata, who was, in turn, a disciple of Gaudapada, who was the author of a renowned commentary on the *Mandukya Upanishad*. Gaudapada's work utilizes a great deal of Buddhist terminology as well as Buddhist forms of argumentation. But it does so in the elucidation of Vedanta, the Hindu philosophy based on the interpretation of the *Upanishads*, the *Brahma Sutras*, and the *Bhagavad Gita*.

Shankara continued in the footsteps of Govinda and Gaudapada, writing many commentaries of Vedic texts that he interpreted in terms of his philosophy of *advaita*, or nondualism. According to Advaita Vedanta, Brahman, the ultimate reality affirmed in the *Upanishads*, is the sole reality. The world made up of the phenomena of ordinary experience is a mere appearance that we superimpose upon the reality of Brahman. To use one of Shankara's favorite metaphors, the world is like a snake that one sees in poor light. On closer inspection, it is revealed that the snake is really a rope that one has not perceived correctly. The world, like the snake, is *maya*. It is neither real nor unreal. It is not completely unreal, for it is based on a truly existing reality: Brahman/the rope. But it is unreal in the sense that it does not have the character that it appears to us to have: the world/the snake. Liberation from the cycle of death and rebirth, according to Shankara, occurs when one perceives reality as it truly is and realizes that all of existence—and in particular the self, or *atman*—is nothing but Brahman. This realization can occur during one's lifetime, and Shankara's followers believe him to have been liberated while still in his physical body (*jivan-mukti*).

God, for Shankara, is the supreme personal form of Brahman, as perceived from the point of view of *maya*. But the distinction between God and the world, and God and the self, is ultimately an illusion to be overcome through right knowl-

edge. The deities of Hinduism—Shiva, Shakti, Vishnu, and so on—are different forms or aspects of the Supreme Being.

Shankara spent a good deal of his career debating Buddhists. But he had Hindu opponents as well, who believed that his doctrine of *maya*—affirming the unreality of the world and the ultimate unity of the individual and the supreme reality—was too similar to Buddhism, undermining popular piety and the practice of devotion (*bhakti*). Shankara saw devotion as a preliminary to knowledge, the true source of liberation. At the same time, while his philosophy did subordinate devotion to knowledge, some very beautiful and intensely devotional poetry is attributed to him. His preferred deity was Shiva.

Shankara saw the greatest weakness of Hinduism, in contrast with Buddhism, to be the lack of a highly organized monastic structure, such as the Buddhists had. He sought to replicate this structure by establishing the Dashanami order of Hindu monks and four monasteries, or *mathas*, at the four corners of India, which are still prominent monastic centers today: Sringeri in Karnataka (in the south), Dwaraka in Gujarat (in the west), Puri in Orissa (in the east), and Jyotimath in Uttarkhand (in the north).

Emergence of Tantric Movements

Tantra is a loosely defined category that incorporates many different beliefs and practices. It is

often opposed to the Vedic and Brahmanical orthodoxy that upholds rigid caste structures. It is likewise transgressive in nature in the sense that Tantric symbolism and ritual defy orthodox social norms. The symbolism of Tantra categorizes the world in terms of numerous categories represented by deities, sounds, and other symbols known only to the initiated. The most important symbols are the ultimate cosmic pair Shiva and Shakti, whose union gives rise to the entire world and all beings within it.

Tantric literature frequently presents legendary stories of its origins. These texts, called *Agamas*, typically present the god Shiva transmitting teachings as revelations. They are often framed as a dialogue between Shiva and the goddess called Shakti or Devi. The legendary quality of these frames reflects the obscurity of finding a starting point for the emergence of Tantra, although the earliest Tantric texts date to circa 600 CE. The word *tantra* comes from the root *tan*, meaning “to extend,” referring to the idea of a web, or spreading fabric on a loom. Tantric traditions point to an etymology that combines the roots *tan* with *tra*, which means “to save,” giving one the sense that salvation lies in the expanse of the world. As a term, it appears before literature that explicitly identifies itself as Tantric, referring to a collection of literature on a subject.

The body itself is the vehicle of salvation in Tantra. Meditation (*sadhana*) aims at uncovering the divine nature within oneself. In particular, Tantric meditation involves visualization of the body as the home of the gods accompanied by the recitation of *mantra* (sacred formulae for chanting). The body is a microcosm whose structure reflects the nature of the cosmos as a whole. The fusion between human consciousness and the physical body is thought to reflect the divine couple, Shiva and Shakti. While different traditions emphasize one or the other of this divine pair, most agree that liberation occurs when one realizes in meditation this cosmic union in one's own body.

Belief in the supremacy of the goddess identified as Shakti (“power”) overlaps with devotional goddess worship. First seen in texts of the seventh and eighth centuries CE, cults of the goddess Kali point to the immanence of the divine in the world. The ferocious aspect of Kali, her

➤ A TANTRIC MEDITATION

Tantric manuals of meditation employ methods cloaked in symbolism and often use methods that locate the divine couple Shiva and Shakti in the body. For example, a ninth-century CE meditation manual called the *Vijnanabhairava* teaches one to identify with Shiva (here called Bhairava) by meditating on the breath. Whereas Shiva is the essence of consciousness, the breath is the goddess, Shakti, alternately drawn in and exhaled out. In meditation one puts awareness on the cycle of respiration and gradually learns to hold the breath in meditation. Then, with this motion stilled, one is supposed to have a vision of Shiva.

—Matthew Bingley

affiliation with jackals, corpses, and cremation, all point to the transgressive element of Tantric rites as a means to liberation. In the Shri Vidya traditions, meditation utilizes geometric diagrams (*yantra*) that represent the goddess in the world as well as various mantra, to come to the realization of the creative force underlying the world. The goddess is also the force underlying the efficacy of Kundalini yoga. In these practices the goddess is a coiled serpent slumbering at the base of the spine; in *sadbhāna* she is roused and made to ascend through the energy centers (*chakras*) to unite with Shiva above the crown of the head. The body, as well as the elements of the Tantric physiology involved, are all seen as aspects of the power of the goddess.

The emphasis on the goddess as divine energy inherent in the physical world forms the basis for so-called Left Handed practices. These are the infamous and secretive rituals involving what are referred to as the Five M's, named for the first letter of each ritual element: wine (*madya*), fish (*matsya*), meat (*mamsa*), parched grain (*mudra*), and sexual union (*maithuna*). While Tantra is often connotatively identified with sexual elements, the extent to which these practices were actually performed, or are symbols representing the divine couple Shiva and Shakti, remains a matter of contention.

The loose collection of traditions that have sometimes been called Kashmir Shaivism repre-

sent a high point in Tantric philosophy in the first millennium. It should be noted, however, that not all of these sects were both Kashmiri and Shaiva. These traditions fused the worship of Shakti with Shaiva Siddhanta and other sects into a form of monistic belief in which everyone and everything is part of Shiva. It was an idealist philosophy in that everything was of the nature of light (*prakasha*) as perceived through the self-reflexive awareness (*vimarsha*) of the Lord. The aim of all *sadbhāna* is to realize one's true identity as Shiva through meditations aimed at clarifying one's own consciousness.

The most comprehensive theologian of this system of thought was Abhinavagupta (ca. 975–1025). His work incorporated the philosophy, practices, and symbols of other Tantric traditions into a synthesis he called Trika (“Three-fold”). This term may refer to the successive levels of attainment one experiences through the purification of consciousness in *sadbhāna*. With Abhinavagupta, Tantric thought and practice reached a zenith in Indian religion. The beliefs of Trika were later to influence Shaiva and Tantric systems in southern India. Some of the practices and iconography are also seen in Vajrayana Buddhism, although the relationship between Buddhist and non-Buddhist Tantra remains unclear.

Esoteric or Vajrayana (“Diamond Way”) Buddhism is similar to other forms of Tantra in that it utilizes a rich symbolism, numerous mantras, and yogic methods in which the practitioner identifies with a particular Buddhist deity. Much as with other forms of Tantra, one cannot definitively point to a specific moment for the evolution of Esoteric Buddhism, although Tantric elements first appear in Buddhist texts in the seventh century CE. A major distinction of this form of Tantra is its assimilation into a Buddhist philosophical and soteriological framework. For example, the virtues of compassion and wisdom replace the duality of Shiva and Shakti. Likewise, any identification with a Buddhist divinity is done with the doctrine of emptiness (*śūnyatā*) in mind: at the end of the ritual, the practitioner deconstructs this notion of selfhood.

With the destruction of Nalanda University, Tantric Buddhism virtually disappeared from India. A sect of Tantric Buddhism appeared in China

in the late seventh century CE. Although it died out in China, it survives as the Shingon sect in Japan. However, Tantric Buddhism successfully established itself as the dominant form of Buddhism in Tibet from the eighth century onward. In this era the Buddhist missionary Padmasambhava, reputed to have pacified the demons of Tibet, established the Nyingma sect. Likewise, the Indian sage Naropa (956–1040) taught Esoteric Buddhist teachings to his Tibetan disciple Marpa, who in turn founded the Kagyu sect in Tibet.

Indian Philosophies, 300–600 CE

The period 300–600 CE was probably the most productive era in Indian cultural history. It was a period during which the arts, literature, and science flourished, and the lively exchange with other cultures, especially China, stimulated the intellectual vitality of the country. For example, the famous Sanskrit play *Shankuntala* by Kalidasa originated during this time. However, the once-common label “India’s Golden Age” is now avoided among historians, who over the last decades have aimed at drawing a more differentiated and evenhanded picture, especially with regard to the social conditions of the time. Similarly, the term “Gupta Age,” after the dynasty that ruled the north for nearly 250 years, has been criticized for neglecting the political diversity of the Indian subcontinent, much of which lay beyond the boundaries of the Gupta empire.

In modern secondary writings it is common practice to group Indian philosophies into six

orthodox (i.e., Hindu) schools (in three pairs of two: Nyaya-Vaisheshika, Samkhya-Yoga, and Mimamsa-Vedanta) and a few unorthodox systems such as the Buddhists and Jains. Yet even the adequacy of the term “Hinduism” is disputed among scholars, and the interactions and codependencies of the numerous Indian philosophies are much more complex than such categorizations suggest. The following examples aim to highlight some central themes and achievements to offer a flavor of the vibrant intellectual climate of the time, but as with most periods in Indian history, the biographical data of the individual philosophers who probably lived during this period are far from universally agreed upon.

While the period between 300 and 600 CE was one of toleration for many philosophies and religions, one remarkable feature was the growing influence of Brahmanism in Indian culture, particularly of the bhakti (devotional) cult. Philosophical discourse experienced an increased use of the high-class language of Sanskrit as opposed to vernaculars such as Pali that had been used by the Buddhists. Sanskrit became the lingua franca for intellectuals across India, thus furthering philosophical exchange between the different regional schools of philosophy.

The Yoga sutras, attributed to the quasi-mythical Patanjali, probably originated during the fourth century CE. These treatises on spiritual and mental discipline, which famously define yoga as the “cessation of the fluctuations of the mind,” mark the beginning of a tradition of textual transmission that has continued into the present time and has expanded well beyond the Indian subcontinent. While the Indian traditions do not ascribe separate realms to philosophy and religion, not all topics of Indian philosophy were essentially spiritual in nature. More worldly topics included the principles and policies of government, the scope of authority that should be granted to a ruler, and the theories of law and social order. Besides explicit literature on law, such issues were often discussed in narrative form such as in the Puranas, sacred legends that in their written form can be dated from the fourth century onward, although the oral tradition stretches much further back.

The study of language had always been a central concern of Indian philosophy, partly

➤ INDIAN LOGIC

The science of proper reasoning developed in India from the study of rhetoric and grammar. In formalized debating competitions there were three types of debate. In tricky debate (*jalpa*) each participant tried to make their position seem stronger, often through clever use of rhetoric. Destructive debate (*vitanda*) tried to defeat the opponent at any cost, without offering constructive argument for an alternative position. In honest discussion (*vada*) both parties sought to arrive at the truth by using only logically acceptable arguments.

For the Nyaya School, a properly formed argument for public debate consisted of five steps, including two concrete examples from experience, one similar and one dissimilar. The standard example of the Nyaya syllogism was: There is fire on the hill (proposition). Because there is smoke (reason). Like in the kitchen, and not like in the lake (examples). On this mountain, since there is smoke, there must be fire (application). Therefore, there is fire on the mountain (conclusion).

This model was accepted by most schools of Indian philosophy, although Buddhist philosophers such as Dignaga thought it too long-winded and took the first three steps as sufficient for a well-formed argument. The Nyaya School accepted this shorter model for drawing conclusions for oneself but insisted on all five steps when trying to convince another person.

—Melanie Mader

because the effective performance of the sacred rituals was thought to depend on the correct recitation of the ancient Vedic texts. Yet far from being a mere handmaid to religion, linguistics was developed into a true philosophical science by philosophers such as the fifth-century grammarian Bhartrhari, whose *sphota* theory was designed to tackle the problem of understanding meaning. According to Bhartrhari, sentences rather than individual words convey meaning, and a message is understood not through a combinatory process of the mind but instantaneously and as a whole.

Based on the rules established by the Nyaya (logic) school, the art of well-formed arguments developed into an important part of Indian culture, where many different schools had to com-

pete for followers and patronage, sometimes in formalized competitions of debate. The origins of the Nyaya sutras, the most fundamental text of this school, are difficult to trace, but the first existent commentary that tries to make these aphorisms accessible was composed by Vatsyayana probably during the fifth century. Such commentaries on texts of authority became a typical feature of the Indian philosophical tradition, with philosophers trying to present new ideas not as their own innovation but as already implied in the established works they were commenting on. Respect for tradition, and especially for the sages and teachers of ancient times, is a defining feature of Indian intellectual culture.

Of the schools that did not accept the authority of the Vedic scripture, the Jains are to be mentioned for their important contribution. Around 400 CE or somewhat earlier, the most fundamental philosophical text of Jainism, the *Tattvarthasutras*, was composed, which deals with, among other topics, ontology (the question of existence), karma theory, and the mechanisms of the soul's bondage in the cycle of rebirths. The Jain philosopher Kundakunda wrote on the two viewpoints from which reality can be perceived: the absolute viewpoint of truth that is available to the omniscient person and the conventional viewpoint that is taken by most people yet, though not necessarily false, is limited and limiting in comparison to the ultimate and all-encompassing truth.

In Buddhism a central development was the increased importance of the populist notion of the bodhisattva, an advanced spiritual seeker who defers final Buddhahood out of compassion for all living beings, opposed to the austere focus on personal liberation that had characterized the earliest *sangha* (Buddhist community). On a more intellectual level, the philosopher Dignaga provided Buddhism with a systematic epistemology and logical theory. His *betuchakra* (wheel of reasons) can be seen as a first step toward a system of formalized logic. The philosophers Buddhaghosa and Buddhadatta produced comprehensive surveys of the central Abhidharmika notions, that is, the Buddhist system of how to advance toward liberation through several stages of meditation. Another important contribution was made by the sixth-century

Buddhist philosopher Dharmakirti, who built on the logical work of Dignaga. For example, on the much debated issue of cause and effect, Dharmakirti concluded that such relations are merely human conceptual constructions and do not possess independent reality.

Indian Philosophies, 600–1000 CE

The time between 600 and 1000 CE can be seen as the transition from late ancient to early medieval India. After the Hun invasions and when King Harsha, whose power had held the kingdom together, died without an heir, countless smaller and often unstable kingdoms came into existence, most famously those of the Rajput clans in the north and west. In the south, however, which was often neglected in older historiographies, no such unitary power had existed even in the preceding centuries, and the simplistic image of an Indian Dark Age, which followed the golden age of the Gupta period, has been shown to be inadequate by more recent scholars.

Despite the often restless political situation, at the royal courts the arts, philosophy, and religion found generous patronage according to the tastes of the local ruler. In the field of philosophy, classical values were still highly regarded, and if this era could not compete with the pre-

ceding in terms of innovation, it was characterized by an increasingly sophisticated and technical application of the fundamental ideas in the form of commentary literature and encyclopedic treatises.

During the seventh or eighth century, the philosopher Shankara was born probably in what is today the southern Indian state of Kerala. The central aspect of his Advaita (nondualist) philosophy is the existence of one Absolute (Brahman) behind the apparent diversity of things. For the Advaita Vedantins the path to liberation consists in realizing that all distinctions, especially between knower and object of knowledge, stem from an ignorant mind-set and are ultimately illusory. The aim of the Vedantins lies in attaining pure, immediate consciousness, which, because it is nondifferent from Brahman, is also thought of as the state of ultimate bliss.

The monistic Advaita Vedanta philosophy is still equated by many people with Indian philosophy per se. This is mainly due to the accounts of Indian philosophical history presented by neo-Vedantins such as Svami Vivekananda, which the West accepted during the nineteenth century without much questioning. Yet besides Shankara's unmatched fame, the Advaita Vedanta school has produced many other original thinkers such as Shankara's slightly older contemporary Mandana Mishra or the tenth-century philosopher Vacaspati Mishra, an extremely learned scholar who wrote for several different schools. It also has to be emphasized that the Advaita Vedanta is not the only form of Vedanta, that is, a philosophical system that grounds itself in the interpretation of the last part (*anta*) of the sacred Vedic texts.

The school that focused primarily on the interpretation of the ritualistic aspects of the Vedas and the concept of dharma (duty, law, religion) was the Mimamsa (exegesis) school. During the seventh century, two branches of Mimamsa developed. The founder of the first was Kumarila Bhatta, of the second Prabhakara Mishra. Both agreed that the Vedas were eternal and authorless and that they manifested their own validity because of the eternality of the Sanskrit language and the correspondence of grammatical structures to the underlying order of the cosmos. Nevertheless, the Mimamsa system also

➤ INDIAN THEORIES OF PERCEPTUAL ERROR

The problem of perceptual error, how a person could mistake a rope for a snake or mother of pearl for silver, was an issue of heated debate among Indian philosophers. For the Buddhists, perception was limited to the intake of a stream of momentary sense data, and any error had to originate during the conceptual construction of the mind. For the Naiyayikas such as Jayanta Bhatta, who objected to such a gulf between mind and world, error consisted in mistaking one real thing for another. The Naiyayikas claimed that at first the mother of pearl was perceived simply as “something bright.” In case of error, this perception triggered the memory not of mother of pearl but of silver, and according to the Naiyayikas, that silver was in reality located elsewhere. Prabhakara found the idea that real silver could be perceived in an erroneous perception absurd and claimed that what was presented was merely remembered silver. For Shankara, the erroneously perceived silver was of a different status altogether. He thought of it as neither real nor unreal but rather that it originated with the illusion and was destroyed at the moment the object was recognized as a shell.

—Melanie Mader

conceded an important role for perception and rational thinking, as a state of inner wisdom was an important preparatory stage for the correct performance of Vedic ritual.

By the year 600 CE the Nyaya (logic) school had effectively amalgamated with the Vaiseshika (atomism) school. The Nyaya-Vaisheshika system aimed at providing a realist philosophy, based on a rigorously applied theory of substances and properties. One of the greatest works of this school is the *Nyayamanjari* by the ninth-century philosopher Jayanta Bhatta, which was written to provide intellectual distraction to the author who had been imprisoned by the local ruler. The *Nyayamanjari* deals with one of the issues that were most disputed among Indian philosophies, namely the question as to what were the means of acquiring valid knowledge of the world. For the Nyaya-Vaisheshika, these *pramana* were perception, inference, comparison,

and verbal testimony, while other schools disagreed on number or interpretation. During the tenth century a further contribution to Indian epistemology was made by the Nyaya philosopher Bhasarvajna, who reflected on the possible theories of error.

Buddhism, which was to largely disappear from India around 1200, was starting to lose ground both as a religion and a philosophy. A comprehensive defense of Buddhism was attempted by Shantarakshita, an eighth-century professor at the university at Nalanda. In his *Tattvasamgraha* he attacked, among others, the views of the chief exponents of the Nyaya, Mimamsa, and Samkhya schools. The ninth century produced three famous dialecticians: Kalyanarakshita, Dharmottara, and Pandit Ashoka. During the tenth century, Ratnakirti elaborated on the theory of momentariness, the Buddhist doctrine that reality is a chain of fleeting moments, especially with regard to consciousness, ideas, emotions, and the perceived self.

In the era under discussion, Jain philosophy was becoming increasingly systematized, as concepts that had been elaborated for internal use were now employed in interschool competition. The Jain logician Akalanka wrote an important commentary on the *Tattvarthasutra* as well as several original works, which were mainly aimed at refuting the Buddhist Dharmakirti. Slightly later, Haribhadra Suri composed a treatise that discusses the Buddhist, Jain, Nyaya, Samkhya, Mimamsa, and Vaisheshika schools. As an innovative and influential contribution of Jainism to Indian philosophy, the theory of *anekantavada* has to be mentioned. This theory teaches that any object possesses an infinite number of attributes about which, in theory, an infinite number of statements can be made from different perspectives.

As these examples show, Indian philosophies not only concerned themselves with spiritual matters but also tried to understand all realms of human experience. Among the most sophisticated issues debated in the early medieval era were the existence of universals such as cow-hood or pot-ness, the question as to whether an effect had to already be preexistent in its cause, and the problem as to whether a relation binding two substances would require a further

relation to bind the substance to itself, thus leading to an infinite regress.

Buddhism in Java— The Early Years

The first extant record of a vibrant Buddhism in Indonesia is the account of the Chinese Buddhist pilgrim Yijing who, on his first voyage to India in 671 to obtain copies of Buddhist texts, stopped in the kingdom of Srivijaya in southeastern Sumatra for six months to study Sanskrit. He reported that Palembang, the capital city of Srivijaya, contained more than 1,000 Buddhist monks who were preaching and doing good works there. Two and a half centuries earlier, another Chinese pilgrim, Faxian, who in 414 had stopped on the north coast of Java, reported that although he saw Hindu ascetics there, he found few traces of Buddhism.

And yet, Buddhist missionary activity, much of it probably emanating from Sumatra, had already begun in Java in the early fifth century and would increase in the centuries that followed. Shortly before or after Faxian's visit, and certainly sometime before 424, the monk Gunavarman, an early prince of Kashmir, stopped in Java on his way to China and reportedly introduced the doctrine of Buddhism there. The spread of Buddhism to the islands around the Java Sea during this same general period is attested to by the Buddha images discovered

there, including the Buddha on the hill of Seguntang at Palembang and another from the Celebes (Sulawesi), both in the Amaravati style and probably dating from the fourth century, and another in East Java that shows fourth- or fifth-century Singhalese influence.

As for Sumatra, just across the narrow Sunda Strait from Java, a group of inscriptions in Old Malay, found in southern Sumatra, attest to the existence there of a Buddhist state whose king had just conquered the "hinterland" of Jambi, an area to the north of Palembang on the east coast of Sumatra, as well as Bangka, a small island lying just off the same coast, and was preparing to launch a military expedition against Java. The land mentioned there, with its center at Jambi, may possibly be identified with a kingdom referred to in Chinese sources that predated Srivijaya and whose king, Sri Varanarendra, sent a Hindu ambassador to the Chinese court between 454 and 464. The same source states that in 502 a Buddhist king, Gautama Subhadra, ruled there and that his son, Vijayavarman, sent an embassy to China in 519, while the anonymous king whose victorious campaign in eastern Java in 682 is recounted in one of these inscriptions is almost certainly Jayanasa, and the kingdom that he conquered, Taruma, may have become the center for expansion of Sumatran influence in Java.

The next stage begins in central Java in the eighth century with a Sanskrit inscription dated 732 on a stele discovered in the ruins of the Shivaite sanctuary (a temple dedicated to lord Shiva) of Chandi Changgal to the southeast of Borobudur, the largest and best-known Buddhist monument on the island. This inscription commemorated the erection of a *linga* (a phallic symbol of Shiva), not in the shrine where it was found but in the "country of Kunjarakunja," the name at that time for all or part of the Kedu Plain to the west of Borobudur. The author of this inscription was Sanjaya, the first of a line of kings or chiefs who ruled in central Java from the early eighth century to the end of the ninth. A later inscription, dated 907, represents Sanjaya as a prince of Mataram, the southern part of central Java. According to another inscription, the second ruler of this line, Panangkaran, was reigning in 778 under the suzerainty or control

of the Shailendras, who had established a parallel dynasty in central Java sometime in the middle of the eighth century.

The origin of the Shailendras of Java and Sumatra is uncertain, since dynastic traditions trace them back variously to different regions in southern and east-coast India, but their sudden appearance was an event of major importance, not only because it brought the greater part of the Malay archipelago under their rule but also because their empire extended as far as Kambuja (Cambodia) and Champa (Vietnam). The Shailendra period is one of the most important eras in the history of Southeast Asia, for they introduced into the areas where they settled some of the greatest cultural achievements of India at that time.

Whereas the rulers of the Sanjaya dynasty in central Java were Hindu, the Shailendras were Buddhist, and under them Mahayana Buddhist art, inspired at least in part by Tantrism, reached a new peak. Their greatest monument, Borobudur, a massive stupa with over 2,500 carved relief sculptures, represents the culmination of this art, and Sumatran-Javanese civilization became a model for other Southeast Asian countries around this time.

About 835 or possibly 840, the presumed date of completion of Borobudur, to almost a century later, around 930, Buddhism might seem to have been dormant because of the lack of examples of Buddhist sculpture or architecture dating from that time. However, an inscription found on the Southeast Asian mainland written on the occasion of the foundation of two sanctuaries in 908 and 911 mentions two pilgrimages to Java to learn Tantric magic, thus attesting to the fact that Java was still at that time a center of Buddhist activity.

Chinese Intellectual History

Politically, the period 300–1000 CE in China is bounded on one side by the collapse of the (Western) Jin dynasty in the traditional Chinese heartland and the establishment of a dynasty in exile (Eastern Jin) at Jiankang (near modern Nanjing) in 317. This was followed by a period of some three centuries of disunity, traditionally called Southern and Northern dynasties, until the founding of the Sui dynasty (581) and its longer-lasting successor, the Tang (618). Officially the Tang lasted until 907, though it had already been much weakened by rebellion since the middle of the eighth century. Following another period of disunity called the Five Dynasties and Ten Kingdoms, the Song was established in 960.

The intellectual climate prevalent among the cultured elite in the fourth century had its source in events more than a century earlier. With the collapse of the Eastern Han dynasty (206 BCE–220 CE) and the subsequent disorder that preceded the short-lived Western Jin dynasty (265–316), the classical and broadly Confucian commentarial tradition that had been preeminent in the Han suffered an eclipse from which it was not to recover until the Song in the eleventh century. As the cultured elite began to doubt the efficacy of the Confucian tradition, there was a renewed interest in other streams of thought that can be traced back to the Warring States period, for instance, Legalism, Nominalism, and Mohism.

More important, during the Period of Disunity, was the rise of a new interest in the ancient Daoism exemplified by such texts as the *Laozi* and *Zhuangzi* and also the Zhou divination manual known as the *Book of Changes* (*Yijing*), a trend that became associated with a movement

called the School of Mysteries (*xuanxue*). Representatives of this movement include He Yan (d. 249), who wrote *On the Nameless* (*wu-ming lun*) and *On Non-action* (*wu-wei lun*); Wang Bi (226–249), who wrote commentaries on the *Laozi* and the *Yijing*; and Xiang Xiu (d. 300) and Guo Xiang (d. 312), who wrote commentaries on the *Zhuangzi*. While it would be fair to characterize the movement's interest as metaphysical or ontological, the tradition of naming it Neo-Daoism might be misleading since the thinkers involved tend to regard themselves as true followers of Confucius, albeit a Confucius who is both a teacher of morals fit for ordering the world and also a sage who understood the inexpressible mysteries of ultimate reality.

Connected with the School of Mysteries is a type of discourse current among the cultured elite called Pure Conversations (*qingtan*). Originally connected with the study of character that formed the basis of recommendations for political office, the practice eventually took the form of salons in which refined participants competed to display their sophistication by discussing philosophical, moral, or artistic topics with witty and eloquent epigrams. The movement came to be associated with contempt for political life and social conventions and, conversely, a preference for nature and spontaneity and art for art's sake. After the fall of the Western Jin and the migration of much of the Jin elite to the south, the Pure Conversation movement continued to be popular in the Southern dynasties, where it exerted a strong influence on elite intellectual life well into the sixth century. The early exponents of Buddhism were conversant with the format and made use of it for their own polemical purposes.

Buddhism, which originally arose in India toward the end of the sixth century BCE, first began to infiltrate the Chinese world in the first and second centuries CE overland from central Asia. In time, it also came by sea via the maritime trade routes that connected the Indian Ocean, Southeast Asia, and southern China. Initially, the new religion had a limited following among the cultured classes in China. But this was to change from around 300 when, thanks in part to the translation efforts of the monk Dharmaraksha (born ca. 230 at Dunhuang), the circles associated with Pure Conversations began

to take an active intellectual interest in certain doctrines of Mahayana Buddhism. The resulting philosophical Buddhism, which brought together elements from the School of Mysteries and Mahayana Buddhism, was to thrive until the end of the Eastern Jin dynasty in the south but was largely unknown in the north.

In contrast to the more speculative traditions of the south, Buddhism in the north first established itself as a predominantly practical and even political orientation. Emblematic of this development is Fo Tugend (fl. fourth century), a magician-monk of Kuchean origins who won the trust of two tyrants of the (non-Han) Later Zhao kingdom: Shi Le (274–333) and his nephew Shi Hu (295–349). With this patronage, Fo Tugend and his disciples were able to build up an organized Buddhist church that was not only the focal point of a popular religion but also supplied monks who influenced the affairs of the court.

One of Fo Tugend's disciples, the Chinese monk Dao An (314–384), compiled the first catalogue of Buddhist writings in Chinese. The work of Dao An exerted a strong influence both in the north, where he founded a center of Buddhist studies at Chang'an, and in the south, where his most brilliant student, Hui Yuan (334–417), worked. In 402 Hui Yuan, together with his disciples and some laypeople, in front of an image of the Buddha Amitabha vowed that they would be reborn in the Western Paradise (*qingtū*, or "Pure Land"), inaugurating Buddhism as a path of universal salvation in China. While familiar with the philosophical fashions prevalent among the cultured elite of the south, Hui Yuan sought to distinguish Buddhism from native Chinese traditions.

Back in the north, the Kuchean monk Kumarajiva (350–413) presided over a great translation effort in Chang'an, building on the foundations laid earlier by Dao An. This project was to make available in Chinese a great collection of Buddhist texts. Kumarajiva was also credited with introducing the dialectic between Conventional Truth and Ultimate Truth, originally a contribution of the Madhyamaka school of Nagarjuna (ca. 150–250), to Chinese Buddhism. The translation effort of Kumarajiva's team, together with that of the Indian monk Paramartha (500–569) working in the sixth century, made possible the

bulk of what was later known as the Old Translations of the Buddhism texts, superseding the Ancient Translations that preceded them. A third wave, the New Translations, refer to those made in the Tang period.

As Buddhism—in an increasing number of different forms—gained ground through the fourth century, there was a felt need to establish true doctrine by going back to the sources in India. The most famous among the earlier part of the period was Fa Xian, who traveled in central Asia, India, and Southeast Asia from 399 to 412; brought back a large number of manuscripts, and made some translations. But it was during the Tang that the activities of the most famous pilgrim and translator of all Chinese Buddhist history, Xuan Zang (602–664), occurred. Leaving China for central Asia in 629, Xuan traveled and studied in much of India before returning to Chang'an in 645. He assembled a team that translated a large number of Indian texts over some 18 years. Second to Xuan was Yi Jing, who traveled to India by sea via Southeast Asia (from 671 to 685) and stayed for many years at the Buddhist center of Sri Vijaya in Sumatra (685 to 695) translating Sanskrit texts before returning to Luoyang.

The four main sects of Buddhism in China are Tian'tai (Heavenly Terrace), founded by Zhi Yi (538–597); Huayan (Garland), founded by Fa Zang (643–712); Qingtu (Pure Land), whose first patriarch was Shan Dao (613–681) but traces itself to Hui Yuan; and Chan (Meditation), whose founding is traditionally ascribed to Bodhidharma (ca. fifth to sixth centuries). Despite its diversity, this is a Buddhism that had been thoroughly sinicized while at the same time impressing itself upon the trajectory of subsequent Chinese intellectual history.

From the fifth century onward, Buddhism at various times enjoyed state patronage but also suffered periodic attempts to reduce the number of monks or otherwise restrict the influence of the Buddhist church. Buddhist tradition speaks of the “four persecutions” under the Northern Wei in 446, under the Northern Zhou in 574, most severely under the Tang in 842–845, and under the Later Zhou in 955. Nevertheless, Buddhism established itself firmly within the Chinese world and reached the peak of its influence under the Sui and Tang dynasties, where it

was an important aspect of China's power and influence throughout East Asia well into the tenth century. Its influence within China only began to decline in the ninth century. Apart from periodic repressions from successive governments increasingly uncomfortable with the power and size of the Buddhist priesthood, the expansion of Islam also resulted in Chinese Buddhism losing contact with its sources elsewhere in Asia by the end of the eighth century.

In addition, a reaction against Buddhism and all perceived undesirable “foreign” influences began to take shape among certain segments of the intellectual elite around 800. Among the earliest manifestation of this new development was a conscious return to the simplicity and clarity in literary style associated with the ancients that was spearheaded by Han Yu (768–824) and Liu Zongyuan (773–819). In the eyes of these champions of the ancient style (*guwen*), since form and content constitute an inseparable whole, the concern for stylistic sophistication that became prevalent after the fall of the Han (exemplified, for instance, in Pure Conversations) was symptomatic of moral decay. Conversely, proponents of the ancient style did not have a purely literary concern: Han Yu, for instance, was an active opponent of Daoist and Buddhist influence at the Tang court and was exiled to faraway Chaozhou (in modern Guangzhou) for his efforts. Through his disdain for Buddhism and Daoism and his insistence upon a return to ancient Confucianism, Han Yu inaugurated a movement that would eventually culminate in the Neo-Confucian revival of the Song period.

■ Introduction: Western Eurasian Non-Christian Religions of Late Antiquity

Christianity and Zoroastrianism were the principal western Eurasian religions in late antiquity (300–622 CE), but there were also several other major and many minor religions. Judaism had a venerable and well-developed tradition, and it, like Manichaeism, another widespread faith of the time, would have a vigorous career through late antiquity and the early medieval age. Mazdakism, an offshoot and heresy of Zoroastrianism, would be the vanguard of a social protest movement in Persia that was brutally suppressed.

During this period, important developments occurred within Judaism. With the destruction of the Second Temple and the dispersal of the Jews in 70 CE, Rabbinical Judaism developed to fill the void left by the lack of central authority in Judaism. Rabbinical Judaism was primarily interested in the transmission and interpretation of the Oral Law in parallel with the Written Law contained in the books of the Bible (the Tanakh). The Oral Law was compiled in the Mishnah by 200 CE. (The function of the Mishnah in Rabbinical legal interpretation can be roughly compared to that of the hadith in Islamic Sharia.) The Talmud, in addition to the Mishnah, also includes the Gemara, or rabbinic discussion and interpretations of the Mishnah. The development of the Talmud was completed about 500 CE, and further revision was declared impermissible. The Talmud is a discussion of Halakha, which is believed to not only encompass law but also to provide a pathway for virtuous life.

Not all Jews agreed with the course of Rabbinical Judaism. The Karaites, an important group active especially in ninth- and tenth-century Baghdad, rejected the Mishnah and the whole concept of Oral Law and insisted that the Written Law derived from the Tanakh was sufficient to provide a guide to living. The conversion of the Khazars to Judaism in the sixth century is sometimes attributed to Karaite missionaries.

Almost all western Eurasian religions, including Christianity and Islam, share a common eschatology, a belief in the place of man in a cosmic history. Western religions are dualistic, see-

ing cosmic history as a struggle between the forces of good and the forces of evil. Most Western religions posit a linear cosmic history, with a belief in an end of times and a day of reckoning whereby the just will gain paradise and the sinners will suffer for their iniquities.

During late antiquity, most Western religious traditions were convinced that they alone possessed the truth, and they persecuted heretics in their midst.

—Wilfred J. Bisson

Zoroastrianism in the Sassanid Period

The story of religion is integrated to the political events in the Sassanid age. The reason is the role of Sassanid kings who claimed to be the owners of both politics and religion. The first Sassanid king, Ardashir I (r. 226–241), announced Zoroastrianism as the official religion in the empire. Generally speaking, Sassanid kings considered

Ardashir I receives his crown from the god Ahura Mazda in this relief. Ardashir I founded the Sassanid dynasty of Persia and aggressively promoted Zoroastrianism. (Paul Almasry/Corbis)

➤ KERDIR—THE ZOROASTRIAN MAGI

Kerdir also made some basic changes and began fighting with other religious groups such as Jews and Christians. This fanatic religious leader stimulated his contemporary kings, Bahram I (r. 273–276) and Bahram II (r. 276–293), to kill Mani and his followers simply because, according to him, they were apostates who abandoned their faith. Kerdir used the same excuse by accusing all of his critics of treason. These cruel policies dissatisfied the Zoroastrian court and, consequently, the Sassanid kings. Such internal conflicts made the Sassanid empire weaker, and this weakness brought failures for Persians in their wars against Romans in their western boundaries (in which Armenia was separated from the Sassanid empire).

—*Mohammad Gharipour*

themselves as representatives of Ahura Mazda on earth. The coinage and rock reliefs that remain from this area show that the kings received the crown from Anahita or Ahura Mazda (as symbols of gods).

In order to understand the development of Zoroastrianism in the Sassanid period, we need to analyze the social context at that time. The Sassanid society was divided into four classes. The first class was royal family, the second class was clerics Magi (Zoroastrian), the third class consisted of military officers, while the common people made up the fourth class. The Magi became more powerful within the state and became either a great source of support for kings or their biggest enemy. In other words, it was the influential Zoroastrian clergy who was ruling the country from behind the scenes. With the support of army leaders and courtiers, these clerics had power to easily enthrone and dethrone kings, especially the kings who were more tolerant of other religions such as Mazdakits and Manicheans. The fact that the kings received their crowns from religious parties clearly shows to what extent the credibility of kings depended on the confirmation and approval of Magi.

Zoroastrianism in the Sassanid period was never similar to the pure and united faith that was common in the Achaemenid period. Various

cults derived from Zoroastrianism but combined with superstition practiced by people in this period. Moreover, the increasing number of Christians after the Parthian period had made Zoroastrian clerics worry about losing their power in the empire. They were also concerned about new religions offered by Mani and Mazdak, which had come to replace the corrupted Zoroastrianism in that age.

In a rivalry with Christians and Manicheans, who had established sets of detailed rules and regulations, Zoroastrian clerics with the support of the king Ardashir decided to collect all of their references in order to come up with an integrated set of rules and material for their religion. Under the command of Ardashir I (r. 226–241), Tansar, who was the chief of Magi, began to collect the lost pieces of Avesta and organized them in a book. But this book was not comprehensive enough to answer all religious questions of people. It also let clerics interpret Zoroaster's teaching in different ways and take advantage of Zoroastrian teachings for their benefit. Because of the lack of unity in religious documents, some even disagree with interpretations and rules used by other clerics. During the reign of Ardashir's son and successor Shapur I (r. 241–272), Kerdir, who was the most powerful Magi (Mobad-e Mobadan), decided to decrease the power of local clerics from local governments in the Parthian age. In order to spread Zoroastrianism in the Sassanid empire, Kerdir ordered the erection of fire temples and fire altars. In fire temples, a sacred flame, believed to have been lighted from heaven, was kept continuously alight by the priests and was spoken of as inextinguishable.

After Kerdir, the most powerful Magi was Mehrespand, who was a wise and moderate clergy. He was also chief of an assembly who announced the unborn son of Hormoz II as the king. Mehrespand's success in finding a king for the empire at that time was a solution for the political conflicts among courtiers. His major role was organizing Zoroastrian documents, disciplines, and thoughts in this period to create unity and to increase concentration of the religious power. With other clerics' agreement, Mehrespand established an assembly that included members of important Magi in the em-

pire who were representatives of different sects. This assembly was formed in order to come up with an overall agreement on interpretations of Avesta. The members of this assembly elected seven of them to finalize these decisions on Zoroastrian religion. These seven Magi elected one who was the most virtuous, Ardaviraf, as the final juror. Ardaviraf claimed that with the help of God and Zoroaster he would choose the best decisions and answers. Because of his important role, people later considered Ardaviraf as a saint and made stories about his ascendance to skies to see the splendor of God. The result of all these discussions among clergies was editing a new version of Avesta in the Pahlavid language that was more like an encyclopedia of various topics from medicine, geometry, astronomy, and other aspects of life. It could resolve many conflicts among clergies and consequently led to a unity in the Sassanid empire that lasted for approximately three centuries. At the same time, it was used as a tool to control people's lives, beliefs, and behavior.

Christensen, A. "Sassanid Persia." In *The Cambridge Ancient History*, Vol. 12, *The Imperial Crisis and Recovery (A.D. 193–324)*, edited by S. A. Cook et al. Cambridge: Cambridge University Press, 1939.

Mazdakit Movement

The Mazdakit movement was a heretical offshoot of Zoroastrianism in the last century of the Sassanian empire. The Sassanian government and the orthodox Zoroastrian priesthood regarded it as a very pernicious heresy, rivaling Manichaeism as a target of their wrath. Mazdakism emerged in the late fifth century and, though suppressed, persisted in some localities until the eighth century. Many view it as a precursor to Iranian Shia, which persists to the present.

Mazdak, son of Bamdad, was a Zoroastrian priest (Mobed) in the sixth century in Fasa (or Nishabur) in Iran. He was probably the follower of Zardusht Khurraگان, a Zoroastrian priest in Fasa who began a reform movement in Zoroas-

trian religion. Beginning to preach his new religious concepts around 484 CE, Mazdak, like his mentor, was deeply committed to the concept of social justice and the welfare of the poor. They offered a revised interpretation of the Avesta (Zoroastrian scripture) that supported their views. Mazdak became the leader of a social revolutionary movement, which resembled the peasant's rebellions that recurrently swept through medieval agrarian societies. The Mazdakits attacked the Zoroastrian clergy—whom they regarded as parasites and oppressors—and the landed nobles, pillaging and burning their property and allegedly seizing their women.

In the ensuing conflict, the Sassanian ruler Kavaad I initially allied himself with Mazdak and the movement but was defeated. The nobles and clergy imprisoned Kavaad and enthroned his brother. The orthodox Zoroastrian forces executed Kavaad's eldest son. Eventually a younger son, Khosrow, who became known as Khosrow the Great, seized power. Khosrow immediately set out to crush the Mazdakit movement. In 524 or 528 CE Khosrow arranged for a religious debate in which Mazdak and his adherents were foredoomed and killed. After that he ordered a massacre of Mazdakits.

Although Khosrow I (531–579), remembered as Anushirvan ("immortal soul"), harshly suppressed the Mazdakits, he enacted reforms that ameliorated the condition of the peasantry and curbed their exploitation by the nobles. Following the general massacre, the surviving Mazdakits settled in remote areas. After the conquest of the Sassanian empire by Muslims, the Mazdakits restarted their activities and gradually developed a system of beliefs that was later incorporated into Iranian Shia.

According to Sassanian governmental regulations, the society was divided into four classes. The first class was the royal family (who had control over all affairs of the society), the second class was the Zoroastrian clergy (Mobeds who played an influential role in making political decisions), and the third and fourth classes were workers and peasants. Mazdak, who was going to establish equality for people within the society, questioned the numerous privileges of the noble class and the clergy. According to his

➤ MAZDAK—ZOROASTRIAN POPULIST

From time to time in the history of organized religions, some feel that the religious establishment has lost touch with and is even exploitative of the common people. In such times, reformers attempt to return the religion to what they maintain was its early purity. Martin Luther and the other leaders of the sixteenth-century Protestant Reformation were in that mold. Like the Protestant reformers, Mazdak tried to purify an established religion of superstitions and fallacies, which were thought to be in contrast to what was explained in early texts. A reformist minority of Zoroastrian clergy, who were also eager to purify Zoroastrianism, supported Mazdak. He explained Zoroaster's ideas with a different interpretation from the traditional reading. Criticizing the Zoroastrian clergy, Mazdak attempted to decrease the importance of religious formalities by claiming that all human beings should be able to comprehend the principles of the universe.

—Mohammad Gharipour

teachings, which were a call for social revolution, all people should have equal opportunities to gain money and education and to marry. In his ideal society, nobody had privileges over others, and everybody should obey the king's commands, which represents God's justice on earth. Mazdak's revolution was mainly a reaction against the increasing power of aristocrats and Zoroastrian clergy, whose exactions depressed the productive sectors of society and the taxpayers. Since the peasants, the artisans, and the ordinary people welcomed his ideas and flocked to Mazdak, his movement was called that of popular justice. Mazdak preached the equality of men and women and prohibited polygamy, which the Zoroastrian priests allowed.

Mazdak accepted the Zoroastrian concept of a dualistic universe, which holds that the two great forces in the universe are good and evil, light and darkness, and between them there is incessant conflict. But Mazdak's theology agreed with that of the Manicheans in holding that good and evil, light and darkness, are inextricably mixed in each individual. The whole world was overshadowed in dark, and a resurrection or re-

birth experience was required to help the light overcome the darkness.

According to Mazdak, the inner soul is always looking for the divine and hates evil. To reach perfection and avoid corruption, one should fight inner greed through creating a simple but comfortable life that fulfills basic needs. Mazdak emphasized good conduct, which involved a moral and ascetic life, not exploiting others unfairly, not making others suffer, not killing and not eating flesh, and being kind and helpful and living in peace with other people while enjoying life. His followers were famous because of their hospitality and mutual support.

Mazdak preached a profound equality among people. Human beings are equal at birth and should share wealth, natural conveniences, and the like. Mazdak taught that the world belongs to God and human beings. All people, regardless of their wealth, gender, and social class, should have the equal right to take advantage of God's blessings. He considered wealth and power as tools to reach prosperity but condemned excess wealth and power as causes of sedition, corruption, and misery. He believed that human beings could reach prosperity in their second life (after death) only if they have a comfortable life in this world.

Mazdak is accused by his enemies of urging people to take advantage of any means to divest the nobles and the clergy of their iniquitous wealth. It has been claimed that Mazdak's movement attempted to establish the world's first egalitarian and socialistic system in a vast empire. For a short period of time it was widely and systematically instituted in the Sassanian empire. Competition between the monarchy and Zoroastrian clergy served to spread Mazdak's movement in the Persian empire.

Changes in Early Medieval Judaism—The Emergence of Rabbinic Judaism

Rabbinic Judaism is the religion practiced by all but a very few observant Jews in modern times. Rabbinic Judaism developed in the first half of the first millennium CE as a result of the Roman empire's destruction of the Second Temple and the dispersal of the Jews from Palestine. When the Romans destroyed the Temple, they also abolished the Sanhedrin, the Jewish court that had been the ultimate human authority on Jewish law. The judges of the Sanhedrin were guided by the Oral Law that was said to have been given to Moses orally on Mount Sinai with the written Torah. The Oral Law was memorized by generation after generation of Jewish students, who learned it by listening to their teachers.

Rabbi Judah the Prince spearheaded the movement to save the Oral Law by having it written down in a compilation called the *Mishnah*. He did this because many of the traditional teachers who had memorized the Oral Law had died in the Great Revolt (66–70 CE) and the Bar-Kokhba Rebellion (132–134 CE). It is estimated that in those two upheavals, about one million Jews died. Previous to these two traumatic events, Jewish legal scholars opposed writing down the Oral Law because of their reverence for the Oral Law and also because they believed that the oral transmission of the sacred Oral Law created a strong bond between teacher and student. The *Mishnah* is a systematic codification of the Oral Law. It is a huge body of work that explicates Jewish law and its application in varying circumstances.

Rabbi Judah the Prince utilized the opinions and rulings of Jewish lawgivers who lived and taught from the destruction of the Second Temple (70 CE) to the beginning of the compilation of the Oral Law in 200 CE. These sages are known collectively as the Tannaim.

Jewish scholars subjected the *Mishnah* to intense scrutiny and interpretation for the next three centuries. Jewish lawgivers searched the *Mishnah* for guidance in forming opinions concerning cases and questions of the law that came before them. These deliberations were then subject to discussion among groups of teachers, or

rabbis. In about 400 CE, a committee of rabbis in Palestine produced the *Jerusalem Gemara*, based on the rabbinical discussions of interpretations on the *Mishnah*. To the *Mishnah* and the *Jerusalem Gemara*, the rabbis added more material on history, mythology, and ethical guidance. These are collectively known as the *Jerusalem Talmud*. A century later, a committee of rabbis in Babylon came out with a more extensive *Mishnah* exegesis, which formed the core of the *Babylonian Talmud*. The *Babylonian Talmud* is what is usually meant when people speak of the Talmud. Rabina (d. 499) is credited with being the chief editor of the *Babylonian Talmud*.

After the dispersal of the Jews from Palestine in the first and second centuries CE, the leadership of the world Jewish community was split: those in the Roman empire initially adhered to the spiritual leadership of a Jewish patriarch in Palestine, while those in the Persian empire were subject to the rule, both religious and secular, of a Jewish prince known as the exilarch who resided in Babylon. The office of exilarch was hereditary in a family claiming descent from King David. The exilarch was legally recognized as the ruler of the Jewish community in the Persian empire. The exilarch instituted religious courts to administer Jewish law and collected taxes from the Jews for the imperial treasury.

In the fifth century CE, Roman emperors abolished the position of Jewish patriarch, leaving the Babylonian exilarch the leading authority in the world Jewish community. It was under the aegis of the exilarch that the rabbis in Babylon compiled the *Babylonian Talmud*.

After the Muslim conquest of the Persian empire, the new rulers recognized the exilarch as the head of the Jewish community (*dhimmi*) in the Islamic world. As head of the Jewish *dhimmi*, the exilarch was responsible for the internal affairs and government of the Jewish community, including collecting the required poll tax (*jizya*). Normally, the Jewish exilarch received his appointment from the Muslim caliph. Exilarchs continued to be appointed throughout this period, but in the twelfth century the caliphal government discontinued the practice.

While the majority of the world's Jews subscribed to the rulings derived from the Talmud,

an important minority refused. These were the Karaites, a religious faction that disputed the central premise of Rabbinic Judaism. The Karaites claimed that the Oral Law, which the proponents of Rabbinic Judaism maintained God had given Moses with the written Torah, was a fiction and that it does not exist. Moses, the Karaites maintain, received only a written law, and it was every Jew's obligation to study the Torah to discover correct modes of behavior for himself. A difference between modern Karaites and the Jewish mainstream is that Karaites insist that one inherits his Jewish identity patrilineally, while the mainstream holds to a matrilineal transfer of Jewish identity. It is not certain if this difference prevailed in the early medieval age. Although there are only a few small communities of Karaites still existing, some historians estimate that in the last centuries of the first millennium CE, a large percentage of all Jews were Karaites. According to some reports, it was Karaite Jews who converted the rulers of the Khazars and convinced them to make Judaism the official religion of an early medieval great power.

The high noon of the Karaites came in the late first millennium. The political competition between Rabbinic Judaism and Karaites became intense. In the eighth century, a line of Karaite exilarchs split off from the main line of exilarchs. The Karaite exilarchs received recognition from some of the caliphs as heads of a separate Karaite *dhimmi*. The Karaites developed their own institutions, and many of their leaders obtained important posts in the caliphal government. By the end of the first millennium CE, the fissure between Rabbinic Judaism and Karaism was deep and permanent.

The Karaites suffered a precipitous decline after the twelfth century. The Seljuk Turks abolished the office of the Karaite exilarch and ceased recognizing a Karaite *dhimmi* independent of the rabbinic mainstream. Without this official support, Karaite Judaism diminished. Rabbinic Judaism became the religion of the great majority of the world's Jews.

Manichaeism

Manichaeism was a minority religion in the Sassanian and Roman empires in late antiquity (ca. 250–650 CE) that spread through central Asia and into China during the second half of the first millennium CE. Although it flourished during late antiquity and persisted for about 800 years more until about 1400 CE, it died out soon after. An offshoot of Zoroastrianism, Manichaeism also included elements of Gnosticism, Christianity, and Buddhism. Manichaeism had a well-organized hierarchical clergy, and it maintained monasteries and female convents and lay congregations.

Manichaeism spread to Rome by 280 CE and Egypt in the 240s. Manichaean monasteries existed in Rome in 312 during the time of the Christian pope Miltiades. In the fourth century, Manichaeism had many followers in North Africa, including St. Augustine, who later converted to Christianity.

In the Sassanian empire the popularity of Manichaeism was seen as a threat to the established Zoroastrianism, while in the Roman empire the rapid growth of Manichaeism was viewed as a threat to not only official Roman paganism but also Christianity. In the Roman empire Manichaeans, like Christians, endured savage persecutions under Emperor Diocletian (r. 285–305). In 296 Diocletian condemned the Manichaeans to death by fire.

After Christianity became the state religion of the Roman empire under Theodosius, Manichaeism was forbidden, and Manichaeans were murdered by Christian authorities. This order resulted in massacres in Egypt and North Africa. Similarly, in 382 Emperor Theodosius I (r. 347–395) decreed the slaughter of Manichaean monks.

Although Manichaeans were suppressed in the Mediterranean, they inspired offshoot sects in Anatolia and Armenia. One sect, the Paulicians, which emerged in the seventh century, had a varied career involving savage persecution by the Byzantine authorities and military conflict

with and eventual defeat by the Byzantine government. In 970 the Byzantine government resettled some of the Paulicians in Thrace, where they served as auxiliaries in the Byzantine army. In Thrace the Paulician settlers inspired the formation of another offshoot sect, the Slavic Bogomils, who in turn influenced the growth of the Cathars, a similar sect in the eleventh century in southern France. The Cathars were viciously suppressed by the Albigensian Crusade in the thirteenth century.

In the east, Manichaeism spread along trade routes as far as Chang'an (the capital of the Tang dynasty in China). In 240 CE Turan Shah, an Indian Buddhist king, converted to Manichaeism. This exposure to Buddhism caused some Buddhist teachings and ideas to permeate Manichaeism.

Similar to their experience in the Roman empire, Manichaeans were savagely persecuted and suppressed in the Sassanian empire and, after the Muslim conquest, by the Muslim caliphate. Manichaeans were under pressure in the Islamic period (except in the ninth century when Caliph Ma'mun tolerated a community of Manichaeans after they were accused of being apostates and were under the threat of being killed).

But Manichaean missionaries had by the fourth century established the faith in central Asia along the Silk Roads and China, where Sogdian merchants had settled. The faith flourished in the Sogdian colonies along the Silk Roads and in the Chinese cities of Chang'an and Luoyang.

During the An Lushan Rebellion (755–763) the Uighur Turks, whose army occupied Luoyang in support of the Tang dynasty forces suppressing the rebellion, became acquainted with Manichaeism. The Uighur khan Bugug (r. 759–780) became a convert and ordered his followers to do likewise. Although this caused turmoil in Uighur society, the Uighurs eventually became Manichaeans, and Manichaeism remained the state religion for about a century before the collapse of the Uighur empire.

Manichaeism was founded by Mani (215–276), born in Babylon, which was ruled by the Persian Sassanian empire. Mani's parents belonged to a Jewish ascetic group, the Elkasites. Later he claimed that he received revelation from a spirit (called Syzygos) and began preach-

Fragment of a manichaean miniature painting with representation of kneeling Hindu gods. From Khocho, Xinjiang province, China, eighth–ninth century CE. (Bildarchiv Preussischer Kulturbesitz/Art Resource, NY)

ing in central Asia, India, and Iran. He taught that salvation is possible through education, abstinence, celibacy, vegetarianism, and fasting.

Mani's activities occurred at a time when competition for political and social power between Christian and Zoroastrian clerics was at its peak in the Sassanian empire. Zoroastrian clerics considered Mani a rival and attempted to use their influence to end his movement. However, Persian monarchs Shapur (r. 241–271) and Hormiz I (r. 272–273) supported Mani. The Zoroastrian magi succeeded in deposing Hormuz because of his support for Mani. Mani died in 276 or 277. While some believe that he died in prison when he was awaiting execution by the Sassanid emperor Bahram I (r. 273–276), others state that he was killed or beheaded. After his death Mani's followers were widely persecuted and slaughtered during the reign of Bahram II (r. 276–293).

MANICHEAN SOCIETY

Mani divided the society into two classes: the class of elected and the ordinary people (laymen). The elect (all males) were the ones who were deemed to have separated their seed of light from their bodies. They were scheduled to live ascetically, not being allowed to marry, eat meat, drink wine, or work. All they did was preach and pray. The laity supported the elect. Although they were not prohibited from getting married, they were cautioned not to have many children because an increasing number of humans would mean that the light was spread in more bodies. The elect were chosen because of their education and family background.

—Mohammad Gharipour

Mani claimed to be a universal savior, the apostle of Jesus of whom Christian texts foretold and the final prophet on earth. He believed that the earlier revelations of the true religion were limited in effectiveness because they were local, not universal. Moreover, he stated that the adherents of these religions had lost sight of the original truth. Viewing himself as the carrier of a universal message destined to replace all other religions, Mani organized an extensive mission program. Despite the pressures from the Zoroastrian Magi and Roman Christians, Mani and his followers spread the new religion in a wide geographical area from west (Mesopotamia, Africa, Spain, France, North Italy, the Balkans) to east (northern India, western China, and Tibet). Because of its wide geographical spread, Manichaeism adopted many ideas from different religions and cultures, especially Zoroastrianism, Buddhism, and Christianity.

Mani was one of the few religious leaders who tried to record his teachings in writing, translate them to other languages, and give those writings canonical status during his lifetime (to avoid any corruption). His seven holy books included *The Living Gospel*, *The Treasure of Life*, *Pragmateia*, *The Book of Mysteries*, and *The Book of Giants*. Except *The Living Gospel*, which was written in Middle Persian, his other books were written in Syriac. His teachings to his students were also collected in other books

such as *Kefalaya*. These manuscripts were later translated to Coptic, Greek, and Chinese. Except a few manuscripts in Coptic and Chinese, not many Manichaean texts survive.

The Manichaean faith was based on dualism. Like his predecessor, Zoroaster, Mani talked about two opposite forces in the world: light and darkness. In his belief the universe is the temporary result of a permanent conflict between the realm of darkness and the realm of light. In opposition to Zoroastrianism, Manichaeism rejects the presence of an omnipotent good power. Human beings, according to Mani, are battlegrounds for two powers: the light (soul) and the dark (body). While the soul is incorruptible, humans' bodies are considered as the sources of evil. Salvation lies in the release of spirit and soul (light) from body (matter) and its return to its original state of separation.

Mani stressed the importance of individual salvation because the light that makes up the human soul cannot be physically redeemed. Its salvation depends on a conscious struggle for virtue by each individual. For Mani, the soul could have two fates before it attains release before final justice. The virtuous souls would leave the body in order to join gods to ascend to the New Paradise, but sinners would go to death (hell). He also believed in an Armageddon as the ending point of the world. He believed that after this great war the light would be drawn out of the world. It would also be followed by the coming of Jesus, who would establish his judgment seat and separate the virtuous people from the sinners. After that the New Paradise would be joined to the Paradise of Light, and its inhabitants, gods and the redeemed, would behold once more the face of what he called the Father of Greatness, hidden from them since the struggle began.

In his theories on creation Mani discussed three separate stages of the creation of gods. He believed that the creation of the world is the result of the victory of the Living Spirit over the powers of darkness. He also believed that the creation of man is the consequence of matter (personified as Greed or Desire) that prompted two great demon-animals to devour the offspring of the other animals and thus to absorb into their own two bodies all the light that they

possessed. The mate of this pair led to the production of Adam and Eve.

Manichaeism among the Uighurs

What distinguishes the Uighurs from other early Turkic tribes is acculturation; this is characterized by the shift from a nomadic way of life, based on pastoralism, to a sedentary way of life, based on agriculture and commerce. In the case of the Uighurs, what prompted their interest in commerce was their proximity to the Chinese empire to the immediate south of them, not only the promise of lucrative trade with them but also the possibility of gaining a certain amount of control over the trade routes passing along the Silk Roads between China and the West. The most salient feature of this acculturation process is not, perhaps, permanent settlements and the eventual building of cities but rather the conversion of the populace to religious beliefs of other older sedentary populations, not in this case to those of China, such as Confucianism or Daoism, but to religions originating in Western countries.

First mention of the Uighurs places them in the very north-central area of present-day Mongolia along the Selenga River, not far south from the lower reaches of Lake Baikal, around the end of the seventh or early eighth centuries. This reference is on a stone monument erected in 735 in honor of the ruler of the eastern Turk or Gok Turk empire (680–740), Bilga Kagan, who had died the year before. According to this inscription, Bilga Kagan, when he was about 33 years of age (in 718), led a campaign against the Uighurs

at some place along the Selenga River where they were living and destroyed their residences, and the people scattered up into the mountains.

According to Chinese sources, the Uighurs were distant descendants of the Hsiung-nu (Huns), and their immediate ancestors were members of a confederation of 15 tribes known as the Tolis, of which they were the chief tribe; up until the eighth century, in China at least, the Uighurs were referred to by this name. In the early seventh century, the Uighurs established an independent kingdom, although the Tolis confederation may have been maintained by some of the tribes. In the Bilga Kagan inscription, the Tolis are referred to as living toward the east and are distinguished from the Uighurs. Around 641 the Uighurs were in control of a new coalition called the Tokuz Oguz.

Following the defeat of the Uighurs by the Gok Turk forces in the Uighur homelands, there must have been a treaty and the establishment of cooperation between them, for Eltarish Kagan, the founder of the second Turk empire, incorporated the Tokuz Oguz into his expanding realm, and subsequently the Gok Turk rulers effectively employed the Uighurs to patrol and govern the northern regions of their dominion (682–692). At the same time, the Uighurs managed to maintain friendly relations with the Chinese.

Considering the location of this first-known homeland of the Uighur on the upper reaches of the Selenga River, even closer than the Gok Turk to the Otukan mountain and forest area, the ancient sacred refuge of the Turkic peoples, we might assume that at this point in their history they still clung to the beliefs of their ancestors. In fact, because of their proximity to this refuge, the Uighurs may have been regarded to some degree as the custodians of Turkic religious traditions.

Since there is no direct evidence in the form of texts or contemporary accounts, it can only be inferred from the scattered references in the inscriptions what these religious beliefs were. It appears to have been a form of animism with two divinities predominating: Tengri, meaning "sky" or "heaven" as a deity or in general, with a specific reference such as *kun tengri* ("sun" as a deity) or *ay tengri* ("moon" as a deity), and Yer, meaning "earth," often personified as the deity of Otukan Mountain or as Umay, goddess of the

earth. And just as in heaven there are great spirits such as sun and moon, on earth there are spirits of land and water.

It is sometimes assumed that these beliefs pertain to shamanism, but this has been based on the observations made by travelers to the area of the Altai region and central southern Siberia of shamanistic practices there among such Turkic tribes as the Altay, Teleut, and Shor, and these practices have been attributed to Turks in general as vestiges of their original religious practices. The Turkic word *kam* (“shaman”) is found in general, though only with that meaning in the languages of Turkic tribes where shamanism is practiced; in Uighur, for instance, *kam* means “sorcerer.”

Taking advantage of a state of unrest in the Gok Turk empire, the Uighurs, at the head of the Tokuz Oguz confederation, enlisted as allies the Karluk and the Basmil, and together in 741 they managed to destroy what remained of the weakened realm and set up a new one of their own in Mongolia, afterward known as the Uighur empire. In the following year it was the Karluk together with the Tokuz Oguz confederation who chose the Uighur *yabgu* (administrator) Kullig Boyla as the first ruler of the empire and conferred upon him the title of Kutlug Bilga Kagan; thereafter members of his clan, the Yag-lakar, became the Uighur royal family.

There are a variety of cultural achievements of the Uighurs that are distinctive and set them apart from other nomadic or originally nomadic societies, but perhaps the most significant of these is the conversion of at least a portion of the populace to Manichaeism. This religion, founded by Mani, who according to tradition was born in 216 CE in Parthia, an ancient kingdom located in what is now northeastern Iran, was outlawed as a heresy within the entire Persian empire, where the official religion was Zoroastrianism. However, in spite of intense persecution, this new religion survived and by the time of the Sassanian dynasty in Persia had crossed the Oxus River into Sogdiana and had taken root there among a receptive population. Thereafter Sogdian territory provided a base for the further spread of Manichaeism both eastward and westward. It was not by contact with Sogdians residing in Chinese Turkestan, how-

ever, that the Uighurs were first exposed to the teachings of Mani but rather within China itself. This took place during the An Lushan Rebellion, a popular uprising against Emperor Xuan Zong who called upon the assistance of the Uighurs to help suppress the rebellion.

In 759 Bogu, the second son of the second Uighur kagan, acceded to the throne under the title of Tengri Kagan, and in 762 the kagan himself occupied the city of Luoyang in Henan Province to protect the Chinese capital Xi-an to the rear of the advancing forces of An Lushan from the area around Beijing and Hebei Province toward the northwest. It was there that the kagan met some Sogdian Manichaean *electi* (“chosen ones”), who not only converted Bogu Kagan but convinced him to proclaim Manichaeism as the state religion of his realm. With the help of Bogu Kagan’s forces, the An Lushan Rebellion was quelled, but of greater significance for the Uighur state was the adoption of Manichaeism, for though the religion itself may not have had much impact on the lives of the common people, the introduction of this new religion into the country brought with it an influx of Sogdians, who began to gain some power as advisers in administrative affairs.

Not all the Uighur people, however, were receptive to the new religion. Bogu Kagan encountered some strong opposition from conservative elements in his own court. As a result, the kagan felt it necessary to issue a law whereby groups of ten people were each to have at their head one man who was responsible for the spiritual welfare of the other nine. This was based on the precepts of Mani himself, in which the community was divided into two classes, the *electi* and the “hearers.” It is not clear whether this edict was meant to ensure complete acceptance of Manichaeism by dividing the entire Uighur population into groups of ten or whether it was a means of control, possibly at the insistence of the opponents to the religion, over those who were already converts.

It was Bogu Kagan’s dependence on the Sogdians that eventually led to his downfall, for in 779, upon the death of the Chinese emperor Dai Zong, there was an attempted mutiny against the emperor’s successor, and the Sogdians at Bogu’s court advised him to take advantage of

the situation and undertake an invasion of China. Bogu Kagan's chief minister, Tun Baga, was strongly opposed to such a move, and when Bogu persisted in proceeding with his plan, Tun Baga apparently felt that he had no recourse except to have the kagan assassinated, together with many of his Sogdian advisers and supporters, and had himself installed upon the throne. This initiated not only a period of anti-Sogdian and pro-Chinese political orientation but also a rejection of Manichaeism and a return to the ancient beliefs of the Turkic people.

The shifting prospects of this religion, however, changed with the accession of different Uighur rulers. In 789, upon the death of Tun, the chief minister El Ogasi, who acted as regent for the heir, still in his teens, reinstated Manichaeism and restored the existing Sogdian contingent in the realm to their former positions of authority. El Ogasi continued to rule after 795 as kagan when the young kagan unexpectedly died, and during his reign the Uighur empire gained strength and flourished until his own death in 808.

Religious Syncretism in China and Christian Europe

Syncretism is a process in which ideas, beliefs, or practices are combined or exchanged between cultures, particularly in the realm of religion. Through syncretism, cultures constantly change through historical and social processes. Those processes result in the mixture of ideas in different manners dependent upon the cultures involved. In nearly every instance in which a religious feature is transferred from one culture to another, it is modified by syncretic adaptation.

This was true of Buddhism in China as well as Christianity in Ireland. Christianity, modified by syncretic processes in Ireland, was then exported to northern Europe.

In the early centuries of the Common Era, the male-dominated Buddhist faith entered China. In this instance, a male god became female, fulfilling a need in Chinese Buddhism for a feminine aspect of the divine. When the Lotus Sutra was translated into Chinese, the compassionate Bodhisattva Avalokitesvara ("The Lord who Regards the Cries of the World") became Kuanyin. Meanwhile, a competing belief system, Daoism, had many female deities, while Buddhism had little room for them. The oldest and most influential Daoist representations of female divinity were found in western China under the Queen Mother of the West. By the late eighth century, female representations of Kuanyin appeared in this same area. The male representation of compassion took on a female face to better incorporate existent needs of Chinese society. For China, competing belief systems resulted in the modification of a set of beliefs to accommodate different cultural needs.

In these same centuries, Christianity expanded throughout late Roman society, exposing an ever-widening group of cultures to the precepts of the faith. The expansion moved beyond the borders of the old empire, encountering cultures that had never been part of Roman influence. Encounters between pagans and Christians did not always result in persecution on either side. In the Ireland of the third and fourth centuries, Christianity was appropriated by an ancient society built around kinship, obligation, and honor. Not only did Christianity change the political and social makeup of the island, but by the seventh century, when Irish monks journeyed to the European continent, they brought with them a changed Christianity. The Irish extended the concepts of lordship and clientage to the relationship between believer and God in the form of the penitential, a simple book designed to allow a priest to guide sinners back into the good graces of God. Christianity was transformed in Ireland and brought to Europe the concepts of confession and penance still in use in the Catholic Church of today. For Ireland, the existing relationship

between lord and client was maintained and extended to accommodate even the introduction of a new God.

Examples like these can be found throughout history and around the world, illustrating the kinds of accommodation and assimilation that occur as cultures incorporate new ideas. Cultures are dynamic and are constantly undergoing syncretic processes that have led to the existing cultures of the modern world. Syncretism does not imply the existence of a pure culture that can be located if layers of mixture and accumulation are removed but instead implies that all cultures are composites and that they will go on changing into the future in complex and often unexpected ways. As the example of the Chinese transformation of a god into a goddess shows, noting the kind of transformations that take place when cultures interact can help

historians to distinguish key components of beliefs and their role in society.

■ Introduction: Christianity

In the early centuries CE, Christianity had become, in a competition with other faiths, a major religious force in the Roman empire. Though by 300 CE Christians constituted a small minority of the empire's total population, they were strategically located in the cities, especially in the eastern half of the empire. In the Roman empire as a whole, Christians probably were a majority in the cities. They had a very effective organization and communications network with a hierarchy of bishops and patriarchs, paralleling and rivaling the apparatus of the Roman state.

Originally a proscribed movement, by the second quarter of the fourth century Christianity was the favored faith of the Roman government. By the end of the century, Christianity had become the official state religion. No others were tolerated.

In the course of the fourth century, an official Christian orthodoxy emerged, and heretical variants were, after that, proscribed and suppressed.

Christianity became the identifying religion of the Roman empire and its successor regimes in the West. Before the emergence of Islam, the

Christian Roman empire opposed the equally intolerant Zoroastrian Persians. The Christian religion spread beyond the limits of the Roman empire to northern and eastern Europe; to Armenia, Georgia, and Mesopotamia; and to the Nubian kingdoms and Ethiopia. Nestorianism, a form of Christianity deemed heretical, spread along the trade routes of the Silk Roads, all the way to China.

Christianity became the vector for the transmission of Mediterranean civilization to the Germans and Slavs. After the collapse of Roman authority in the western half of the empire, Christianity developed two centers of religious governance, Rome and Constantinople. The bishop of Rome, the pope, would head the Western Church, which became known as the Roman Catholic Church, while the Eastern Church, governed by the Byzantine emperor and the patriarch of Constantinople, came to be known as the Orthodox Church. The structure of the Roman Catholic Church is often credited with preserving Greco-Roman civilization in western Europe during the Dark Age of late antiquity and the early medieval period.

From the emergence of Islam to beyond the end of the medieval age, western Eurasia would be divided between mutually hostile Christian and Islamic regimes. The advancing Muslims in the first half of the seventh century conquered many of the most populous and devout Christian provinces of the Roman empire, such as Egypt and Syria. For most of the rest of the first millennium CE, Christian regimes were on the defensive against powerful Islamic states. Christian civilization had declined everywhere.

—Wilfred J. Bisson

Constantine and the Christian Revolution of the Fourth Century

The Christian revolution of the fourth century involved the abandonment, by the Roman government, of Roman-Hellenistic paganism and the embracing of Christianity as the legitimizing religion for the empire. At the beginning of the fourth century, Christianity was considered by many Romans to be but one of several mystery religions in the empire. A minority despised by the ruling establishment, Christians suffered sporadic persecutions as Roman emperors attempted to impose religious conformity. Roman-Hellenistic paganism traditionally lent support to the imperial government by its teaching that the reigning emperor was divine. Toward the end of the third century and the beginning of the fourth century, this pagan support was less efficacious because of the medley of mystery religions pervading Roman society. With the Christian revolution, Christianity changed its status to become the religion that enjoyed imperial favor. It replaced paganism in providing sacred sanction for the imperial government.

The spread of Christianity and its eventual establishment as the official religion of the Roman empire can be traced to the developments surrounding the ascension of Emperor Constantine (who claimed the imperial seat in the West in 306, became coemperor in 313, and became sole emperor in 324) and the Council of Nicea (325). A legend, reported as fact by an early Christian historian, Eusebius, has it that Constantine's victories in the civil wars by which he gained power were divinely assisted. In particular, before the Battle of Milvian Bridge, Constan-

➤ CHURCH POLITICS IN THE TIME OF CONSTANTINE—HOSIUS OF CORDOVA, CIRCA 256–358 CE

As one of few Latin bishops who attended the Council of Nicea, Hosius of Cordova was an influential figure in the Arian controversy. Although Cordova rested in the western part of the Roman empire, Hosius corresponded regularly with Emperor Constantine. Prior to the Arian Controversy, Hosius served as an adviser to the emperor during the Donatist schism, which involved questions concerning members of the Church who had recanted their Christianity during the Great Persecution (303 CE) and who now sought readmission to the Church. When the conflict between Alexander of Alexandria and Arius erupted, Constantine enlisted the aid of Hosius to act as an intermediary and carry a letter from the emperor to the disgruntled parties. Following this failed attempt, Hosius traveled to Nicea to preside over the council, although whether he functioned as a representative of the pope or emperor is unclear.

A staunch and unbending supporter of the Nicean Creed, Hosius continued to play a role in theological controversies after the death of Constantine. Presiding over the later Council of Sardica in 343, Hosius met other bishops in a failed attempt to settle the continuing storm surrounding Arius's teachings. Hosius was present at the later Council of Rimini (357 CE), called at the behest of Emperor Constantius II. Often contributed to his advanced age, Hosius signed the Second Sirmian Formula (357 CE), which argued against the use of the word "substance" in the Nicean Creed. The events of the last years of Hosius's life are unknown.

—Dorothy de F. Abrahamse

tine saw a cross in the heavens bearing the inscription *In Hoc Signo Vincas* ("In This Sign Conquer").

The Edict of Toleration (313) allowed Christians freedom to practice their religion. It gave Christianity the status of a recognized religion. It did not outlaw paganism, and there is some doubt as to whether Constantine understood the exclusivity of monotheism. However, with this move, Constantine became the patron of

➤ JULIAN THE APOSTATE (332–363 CE)

Julian was emperor of Rome during 361–363. Referred to as Julian the Apostate because he turned from his Christian upbringing to embrace paganism, he unsuccessfully attempted to halt the spread of Christianity in the empire.

During his childhood, Julian enjoyed a classical education that instilled in him a love for Greek literature and learning. Although he later received instruction in Christian theology, he always remained interested in the classics. Once he became emperor, he acted to limit the influence of Christianity, perceiving it as subversive and dangerous to the stability of the empire. He prohibited Christians from teaching rhetoric, arguing that they could not teach secular subjects objectively. He wrote several letters and treatises that emphasized Christianity's Jewish heritage, noting that the Jews did not recognize Christ as a fulfillment of Jewish prophecies. Julian even mused about rebuilding the Jewish Temple in Jerusalem to disprove the commonly held opinion that the fall of the Temple was a sign of Christian victory. As an alternative to Christianity, Julian tried to revive an interest in paganism. He encouraged pagan priests to emulate Christian attitudes toward charity and adopt a holy lifestyle like that of Christian preachers.

Julian's efforts failed. By the mid-fourth century, Christianity was an established religion and too widespread for Julian's reforms to be effective. Julian's successors to the throne promptly rescinded his legislation against the Christians. In 380 Christianity became the official religion of the Roman empire.

—Lisa Holliday

Christians, and much governmental financial support was withdrawn from pagan temples and rituals and was transferred to Christian churches and ceremonies. His patronage of the faith and his convoking in the Council of Nicea further legitimated Christianity to Romans, particularly the upper classes, thus beginning the intertwining of Christianity with Roman government and its promulgation among the Roman elite.

Constantine's new capital, named Constantinople, was to be the first Christian city. Christian clergy, not pagan priests, conducted the dedication ceremonies. Dedicated in 330, Con-

stantinople boasted numerous churches and was viewed as a safe haven for Christians. Constantine favored the church with a variety of gifts and offered Christians incentives to move to Constantinople. Through legislation, he enforced Sunday as a day of rest and lavished generous funding on churches. Christian leaders turned to him to arbitrate disputes, and he employed an adviser for ecclesiastical affairs. It was in this dual role as patron of the church and Roman emperor that Constantine was drawn into the Arian Controversy.

The Arian Controversy was one of the most vicious and divisive storms to challenge unity in eastern Christianity in late antiquity. It concerned the question of the relationship of the Son to the Father: was the Son a creation of the Father or eternal with the Father? To Arius, a priest in Alexandria, Egypt, the answer to this question rested with the substance of the Son being different from that of Father. Therefore, Arius asserted that the Son was a created being and of a lesser dignity than the Father.

The bishop of Alexandria, Alexander, was unable to stop the spread of Arius's teachings, which soon included powerful figures such as bishops Eusebius of Nicomedia and Eusebius of Caesarea, the noted father of church history. The dissention escalated to effectively divide the Eastern Church. Constantine tried to stop the dispute between Arius and Alexander through a series of letters but to no avail. After a failed council held at Antioch under the supervision of Constantine's adviser Hosius, Constantine called the first ecumenical council to be held at Nicea in 325.

Over 200 bishops attended the council, almost entirely from Eastern churches. Though the degree to which he presided over the council is debatable, Constantine urged the bishops to come to a compromise. While the actual minutes of the council are not recorded, eventually Arius was anathematized, as were two bishops who continued to adhere to his interpretation. These two bishops were exiled by imperial decree. Later Eusebius of Nicomedia joined them in exile.

The Nicene Creed established that the Son is homoousian, or of the same substance as the Father. Containing 20 canons, or laws, the council

also discussed behavioral standards for the clergy and details of canon, or church, law. Nicea was a watershed in Christian history. Regarded as the first ecumenical, or universal, council of the church, the council established written standards of belief and behavior for the entire imperial church and marked the beginning of the Christianization of the Roman empire. Constantine's patronage of Christianity and his participation in the council set a precedent for later relations between emperor and church. Emperors intervened freely in church affairs to settle questions regarding heresy and in some cases to advocate for the primacy of one church over another.

Though the conversion of Constantine and his later relationship with the Christian Church did not result in large-scale conversions during his lifetime, it did begin the process of the conversion of the aristocracy, the powerful senators and wealthy landowners who sought to curry favor with the emperor by converting. Following the model of Constantine, they began to patronize the Church. It became acceptable for sons to embark on ecclesiastical careers rather than secular ones.

Christianity did not become the official religion of the Roman empire until the reign of Theodosius I (346–395, r. 379–395). In 380, with the Edict of Theodosius, he decreed that all citizens of the empire were to be Christian, thus outlawing paganism. He shut down pagan temples and proscribed and outlawed heresy but tolerated Jews.

Christian Orthodoxy and Heresy in Late Antiquity, circa 300–451 CE

When Roman emperor Constantine legalized Christianity in 313 CE, making a previously marginalized, fractured, and quibbling religious group into a powerful institution, the question soon arose of what exactly constituted the right form of Christianity. What was to be orthodoxy (from the Greek *orthodoxos*, meaning "straight thinking")? Although by the beginning of the fourth century proto-orthodox Christianity (the form that would become dominant after Constantine) had succeeded in Rome to become a dominant group, the Christianization of the Roman empire consisted of a process of self-definition that attempted to eradicate all other expressions of the faith. This development was the construction of a monolithic form of Christianity out of the original state of Christianity, which was initially characterized by diversity.

From Christianity's very inception, different groups within it defined correct faith in different ways. Some Christians focused on Jesus's teachings as if he were a philosopher, such as those who accepted the gospel of Thomas. Others saw salvation in Christ's death and resurrection, as did the proto-orthodox. Still others thought Christ too divine to actually suffer and die, such as the Docetists of the second and third centuries. Throughout the first three centuries of Christianity's expansion, Christians argued over who was right. While many supposed *they* were right, they accused other Christians of heresy (from the Greek *hairesis*, meaning "choice"). Of course, no Christian group ever claimed to be heretical; they were rather only accused as such by their opponents. Thus before Constantine, orthodoxy and heresy were simply a matter of perspective.

When Constantine embraced a particular form of Christianity, the *ecclesia* or Church, this family squabble took center stage. It was only a matter of time until the Church would once and for all settle this dispute in its favor. The making

Mosaic shows Christ “of one being with the Father,” from San Apollinare in Classe, Ravenna, mid-sixth century. (Scala/Art Resource, NY)

of orthodoxy took more than three centuries, from around the middle of the second century to the middle of the fifth, with the Council of Chalcedon in 451, and even then the issue of correct belief was not completely settled throughout the Christian world.

It is unclear just how many forms of Christianity there were in the first few centuries. The expert on heresies, Epiphanius of Salamis (315–403), claimed that there were more than 60 variants while he was bishop, while others maintained that there were nearly 130 in other places in the Roman empire. Writings against opposing Christianities demonstrate that the “orthodox” felt threatened by the sheer number of “heretics,” who oftentimes outnumbered them. For example, in the middle of the fourth century Arianism was a majority belief, even accepted by successors of Constantine. By the beginning of the fifth century, the Apollinarian “heresy” was the majority in the Greek-speaking eastern empire. By the 450s the Monophysite Church, influenced by Apollinarius’s Christology rejecting the dual nature of Christ, held sway in a great swath of the eastern empire extending to the Black Sea.

One way to demonstrate the construction of orthodoxy is to examine the case of Christology (the understanding of the nature of Christ). At the forefront of the Christological controversy in

the fourth century was the Alexandrian presbyter Arius, who attempted to define the relationship between God the Father and Christ the Son in terms of hierarchy. Arius’s position had precedent in Origen of Alexandria’s (ca. 185–251) theology, seeing Christ in a subordinate position to God the Father. This conformed well to popular neoplatonic teachings that stressed a cosmological hierarchy from the One (or God) down through lesser divine beings such as angels and demons. Arius’s position, therefore, was in line with popular pagan and Christian philosophical notions of the relationship between the One God and God’s emanations, or divine beings who proceeded from the One. For Arius, Christ was divine but subordinate to the Father. The orthodox position, such as that supported by Alexander of Alexandria (d. 328), objected to the notion that Christ was made at some point in time and stressed the coeternality of the Son with the Father. This was not simply an academic argument but instead had ramifications for the saving act of Christ since, the orthodox argued, this depended upon the savior being God himself.

In the 320s Arius proposed a counter to Alexander’s objection, maintaining that Christ was *homoiousios* (“of like substance”) with the Father, thus being similar but not identical to God the Father. In 325 this formulation prompted the Council of Nicea, a gathering of bishops from around the empire called by Emperor Constantine. It was here that the Nicene Creed, emphasizing the equality and distinctiveness of the three persons of the Trinity and asserting that Christ is *homoousios* (“of the same substance”) as the Father, eventually won the day. This creed was created to combat the Arian position, where the Christological formula that Christ is “eternally begotten of the Father” and “begotten, not made, of one being with the Father” and “through him all things were made for us and for our salvation” emphasized the Christological and soteriological solution. This solution made heretics out of Arius and his supporters. Nevertheless, the council did not settle the debate but instead only created opposing sides. In the mid- and later fourth century, emperors (except Julian) vacillated between pro- and anti-Nicene positions, while each side attacked their “hereti-

➤ LIFE AND DEATH OF THE GREAT HERETIC ARIUS (CA. 260–336), AS REPORTED BY HIS ENEMIES

The life of Arius is difficult to reconstruct with certainty since most of what we know of him comes from his opponents. His own works were systematically destroyed, though a few fragments survive. In general, Arius was a presbyter, theologian, and ascetic. Prior to his condemnation at the Council of Nicea, he was well respected in the Church for his devotion and flair for biblical exegesis. While in Alexandria in 320, Arius raised objection to Bishop Alexander's sermon that stressed the coeternality of both God the Father and the Son. Arius maintained that the Son had a beginning and was created. Alexander condemned Arius, who then petitioned the bishop of Nicomedia for support. Arius was then excommunicated by Alexander from Alexandria for his Christology. Arius then fled to Nicomedia to unite with supporters there. Shortly thereafter Arius's position was proclaimed orthodox by a synod held in Caesarea in Palestine. Arius's position was then publicly supported by Eusebius of Nicomedia. At the Council of Nicea, Eusebius was himself excommunicated for his support of Arius, and the synod of Caesarea was discredited. Moreover, the council of over 200 bishops officially repudiated Arius's teachings and formulated the Nicene Creed and formally declared the *homoeousian* theology. Ironically, the pro-Nicene position was not universally supported. Furthermore, Arius was supported by Emperor Constantine, who

believed that Arius's position was not well represented at the council. Arius was brought out of exile in 328, apparently feeling vindicated somewhat even though he was never rehabilitated into the Church. The fifth-century Orthodox Church historian Socrates describes Arius's death in a very ignominious manner:

"As he approached the place called Constantine's Forum . . . a terror arising from deep regret seized Arius, and a violent diarrhea began to take hold. He then asked whether there was a convenient place nearby to use the restroom, and being directed to the back of Constantine's Forum, he rushed toward it. But soon he became faint, and while he relieved himself, his bowels protruded, followed by a tremendous hemorrhage and the small intestines fell from him. Furthermore, portions of his spleen and liver were expelled in the effusion of blood, so that he died almost immediately."

Of course, this account says much more about how orthodox Christians attempted to humiliate their heretical opponents than how Arius probably actually died.

Socrates Scholasticus, *HE* I.38.

cal" enemies. The Goths were converted to Arian Christianity, which spread the theological argument into Europe in the early Middle Ages.

The Council of Chalcedon in 451, among other things, attempted to eradicate final diversity in how Christ should be understood. The orthodox solution proposed that Christ had both human and divine natures that together form one unified divine person, the Godhead, who also included the Holy Spirit. The question arose, was Christ actually human? If so, how could he also be God? The orthodox position from Nicea proclaimed that Christ had two natures, both human and divine. This was a difficult theology for some otherwise orthodox thinkers to accept. For example, Bishop Apollinaris of Laodicea (d. 392) taught that Christ was too divine to be

fully human. For Apollinaris, Christ entered into the human realm cloaked by a man's flesh, and thus he did not share human frailties. Apollinaris stressed the essential unity of the Father and Christ, maintaining that there was no human subject in Christ but that he was rather entirely divine. Although this form of Christology was proclaimed heretical at the Council of Constantinople in 381, this Christology was reflected in the Eastern Monophysite churches (from the Greek *mono physeis*, meaning "one nature").

Another side of the Christological debate was held by Bishop Nestorius of Constantinople (381–451), who was also proclaimed a heretic by the orthodox supporters. He was, ironically, an ardent heresy hunter and critic of what he considered impious teaching. Cyril of Alexandria

(375–444) was his chief rival and attempted to gain control over the see of Constantinople. Nestorius's first dealings with controversy were over naming the Virgin Mary Theotokos "Mother of God." He maintained that the title "Mother of Christ" was a better title since it could prevent unacceptable confusion about the role of Mary in salvation. Mary Theotokos was extremely popular among eastern Christians in general, and this brought Nestorius into conflict with Emperess Pulchra (399–453), who modeled the Theotokos on her own personal piety and public displays as a pious virgin. This was the perfect opportunity for Cyril to attack Nestorius's own Christological concerns. Nestorius's refutation of the Theotokos title was rooted in his Christology. He warned against the dangers of confusing the human and divine natures in Christ. He was deposed at the Council of Ephesus in 431, his works were ordered burned by Emperor Theodosius II in 435, and he was exiled the same year to a remote Egyptian desert. Nestorianism is actually a distorted version of Nestorius's teachings, falsely crediting him with beliefs that he explicitly condemned. This Dyophysite Church, which arose during these Christological debates of the fifth century, argued that the second person of the Trinity was two persons: the man Jesus who suffered, died, and rose from the dead and the divine Logos who was divine and unbegotten. Christ thus had two natures (*dyo physis*), both divine and human. This Christology emphasizes the distinction between Christ's human and divine natures as opposed to the orthodox emphasis on the unity of both natures.

From the perspective of the Roman emperor, the construction of Christian orthodoxy was also important for political unity. Much like the pagan Roman empire, when religious loyalty meant the insurance of Pax Deorum (Latin for "Peace of the Gods") and therefore Pax Romana ("Peace of Rome"), doctrinal unity might also grant the Christian empire divine peace and prosperity under the direction of its new God. Thus, those forms of Christianity that fell out of favor with the emperor and the Church councils were not only heretics but also traitors. This was the case for the so-called Donatists, whose doctrine was nearly identical with the orthodox except they were critical of Church

leaders who turned over Christian texts to the authorities during the Great Persecutions under Emperor Diocletian, arguing for their excommunication. Their hard-line position was condemned by Augustine in the early fifth century, who preached acceptance of bishops who sold out and maintained that the state was justified in persecuting the Donatists and confiscating their property. The emperor's condemnation made the Donatists a group of political outlaws, not just religious schematics. Orthodox emperors, with their ecclesiastical advisers, persecuted heretics as well as the pagans. This was true with the Monophysites, who in Upper Egypt from the fourth century were the dominant form of Christianity. They opposed the decisions at the Council of Chalcedon and were thereby in direct opposition to the emperor in Constantinople, continually bristling with Byzantine plans to unify Egypt. Byzantine emperors tried to undermine their power in the region, but they were largely unsuccessful. When Egypt fell to the Arabs in 640, the Monophysites treated the Muslims as liberators from their orthodox persecutors. Their Muslim overlord protected the Monophysites from orthodox persecutors so well that even today most Egyptian Christians (Copts) are Monophysite.

Copts in Egypt

In many ways, the experience between 300 and 1000 CE of the Copts, the indigenous Christian community of Egypt, included their highest and lowest fortunes. The fourth century marked the age of Constantine and the end of the great persecutions of late antiquity, and it was also the era of the influential Bishop Athanasius and the emergence of Christian monasticism, with Egypt at its center. By the end of the millennium, however, the Copts had suffered through antagonism from eastern Rome and had succumbed to the political hegemony of Islamic rule and (to a degree) its religious dominance. Coptic society demonstrated remarkable resilience during these centuries.

The prominent position of the Copts in the fourth century was best embodied by Athanasius of Alexandria, the “Father of Orthodoxy” throughout the theological controversies of that time. He was an influential bishop and theologian, but he also played a crucial part in the formation of another institution of Christian Mediterranean life: monasticism. In 357, Athanasius published a biography of Anthony the Great, the most celebrated Egyptian ascetic to withdraw to the wilderness for a life of meditation and prayer, shortly after his death. The text became a classic in the Mediterranean world and beyond, inspiring the spiritual discipline of no less than Augustine and Jerome and leading thousands of others to embrace this form of asceticism. It is no wonder, then, that Athanasius claimed that Satan himself appeared to Anthony, blaming him for the catastrophic growth of desert piety and driving him and his minions out of their territory! Monasticism, in fact, remained central to Coptic identity, even as it became a curious meeting ground of traditions for centuries to come; for example, the Egyptian and Syrian patriarchates maintained neighboring and friendly communities among the monasteries of Wadi al-Natrun through the Middle Ages. More astoundingly, after the arrival of Islam a number of the monasteries that bordered urban areas in Lower Egypt served as fine hunting lodges (with the best wine, scenic views, and iconographic artwork) and retreats for a surprising number of Muslim rulers.

Political tensions between Constantinople and the prominent patriarchates of Alexandria

(Coptic) and Antioch (non-Coptic), chief among them, eventually found their way into the most potent area of controversy of the day: theology. The Council of Chalcedon (451) declared these communions anathema, a decree fundamentally that was based on a doctrinal dispute over the divine/human nature of Christ but also led to the convenient end result of excommunicating Constantinople’s main rivals for ecclesiastical prominence. For an empire that increasingly identified itself as much with its adopted Christian faith as with its Roman legacy, this doctrinal dispute also created a bitter political division between Constantinople and the Copts in its Egyptian province that lasted for another two centuries. Constantinople favored a loyal group of followers (Melkites) who largely consisted of the Greek-speaking elite classes of Alexandria, going as far as to appoint its own rival patriarch to that city. The Coptic dissidents, with their support base largely found in rural Egypt (that is, most of the population of the day), rallied around their local identity by adhering to their traditional patriarchate, their unique Coptic language (a combination of colloquial Egyptian, Demotic, and Greek), and increasingly, to the doctrinal position of their split from Chalcedon.

The dispute with Constantinople did not determine the entirety of the Coptic experience during these years, of course. Daily life remained normal around the Mediterranean, in large part: Syrian hermits remained likely to hold their Egyptian desert fathers as life models, and traders from Constantinople and Antioch continued to regularly bring their goods into the harbor of Alexandria, making sure to leave plenty of time to share bread and wine with their Egyptian counterparts. Even the Coptic patriarchate retained a certain measure of regional influence, particularly in the south where it had extended its ecclesiastical authority over the Christian kingdoms of Nubia and Ethiopia since the mid-fourth century. Until 1000 CE and long after, for example, the Coptic patriarch continued to appoint the *abuna*, the head of the Ethiopian church, from among the ranks of the Egyptian clergy. The tensions beneath this uneasy status quo between Alexandria and Constantinople were not to remain in check indefinitely, however.

➤ DID FAITH MOVE MOUNTAINS?

The Fatimid caliph al-Mu'izz enjoyed a curious relationship with his Coptic subjects. The *History of the Patriarchs of the Egyptian Church*, the Coptic Orthodox Church's official early and medieval history, tells the story that he once invited the patriarch Abraham (r. 975–978) to represent Christianity in a religious debate with the *wazir* (prime minister), a Jewish statesman by the name of Yaqub Ibn Killis. After Abraham managed to dominate the debate, the Ibn Killis responded by pointing out to the caliph that the Christian Gospels promise that even the simplest faith is able to move mountains. Al-Mu'izz, intrigued, ordered Abraham to prove this or lose the entire Coptic community if he failed. Although the patriarch was terrified, the author of *Patriarchs* maintains that a miraculous vision led him to a one-eyed tanner and miracle worker named Simon, who saved the day by standing before the ruler and leading a congregation of Copts in prayer, with the result that the Muqattam Mountains, the hills that loom over the city of Cairo, repeatedly raised high enough that all could see the sun and horizon beneath them. Coptic popular tradition in fact maintains that the caliph himself immediately converted to Christianity, although this particular plot twist remains unsubstantiated by outside historical evidence as of yet.

History of the Patriarchs of the Egyptian Church, Known as the History of the Holy Church, Vol. 2, pt. 2, Khaël III-Senouti II (A.D. 880–1066).
 Translated and annotated by Aziz Suryal Atiya, Yassa 'Abd al-Masih, and O. H. E. Burmester.
 Cairo: Société d'archéologie copte, 1948.

The experience of the Copts changed dramatically in the aftermath of their brief occupation by Persian armies from 619 to 628. Following his reconquest of Egypt and the eastern Mediterranean by 628, the Roman emperor Heraclius (r. 610–641) asserted his authority by solidifying the Christian identity of his empire: this included enforcing Constantinople's orthodoxy and cracking down on those dissident communi-

ties, such as the Copts, that rejected it. For the next decade, this meant that the Church of Alexandria and its Egyptian population—by then a distinct sect from its Melkite rival—faced intense military and economic pressure from the emperor.

It is perhaps of little wonder, then, that the Copts breathed a collective sigh of relief when 'Amr Ibn al-'As led his Muslim army into Egypt in 640–641, successfully claiming the land for this new religio-political community and at first asking only a minor tax for non-Muslims in return. The Copts did not assist the Islamic army en masse in its conquest of Egypt; instead, their role was largely one of passive compliance, as they had little notion that the conquest represented the reign of a new, distinct, and permanent order. In fact, they quickly settled into a *détente* with the Muslim presence and its administrative center Fustat, near the former Roman garrison and local trading center of Babylon. Large-scale conversion to Islam was a process of centuries, not decades, and for these early centuries there is evidence that the growing number of Copts who converted to Islam did so for economic and political benefits. The succeeding Umayyad and Abbasid regimes were, in fact, surprisingly reticent to encourage mass conversion at the risk of losing their substantial tax base of the *jizya* (a poll tax on non-Muslims).

The deeper ramifications of the conquests only became clear as conversion neared a majority of the population (likely by the ninth or tenth century) and as Muslim rulers continued to flesh out their own policies. In 705, for example, the caliph Abd al-Malik made Arabic the language of all official business throughout his lands. This was a blow to the Copts for whom the Coptic language had served to reinforce their distinct communal and ecclesiastical identity under both the Greeks and Muslims. This shift did allow Copts for generations to dominate the scribal classes (given their long-held multilingualism), but it also highlighted the sea change in Egypt's social, political, and religious milieu. There were, in fact, communities that resisted Muslim rule: outright rebellions erupted on several occasions among Coptic villages in the Nile Delta during the eighth and ninth centuries, and the last one in 832 apparently marked that commu-

nity's final resignation to their permanent status as Muslim subjects.

The last decades of the following century, however, brought some of the most prosperous and colorful experiences of the Coptic tradition as Egypt became the center of the independent Fatimid dynasty in 969. The first two Fatimid rulers in Egypt, al-Mu'izz (r. 953–975) and his son al-'Aziz (r. 975–996), immediately recognized the practicality of courting their Coptic subjects: as a dynasty of Shia and therefore distrusted by the dominant Sunni community, they actively sought the favor of local minorities. The Copts represented the primary such group, one that also happened to have generations of useful experience in government administration. Copts thus played key roles in the upper echelons of the Fatimid state and enjoyed remarkable liberties during these three decades; the historical record reflects mostly cordial interaction in those years among the country's Christian and Muslim populations, especially at times of festival and celebration.

The Catholic-Orthodox Divergence to 1000 CE

During the era circa 300–1000 CE, the Christian church was characterized by a growing sense of distinction between the Latin members of the Western Roman church and the Greek members of the Eastern Byzantine Church. This diver-

gence involved a series of disputes over ecclesiastical hierarchy, doctrine, and rites. These religious differences between Latins and Greeks (or, in modern terms, Catholics and Orthodox) reflected and were reinforced by a broader sense of political, cultural, and economic competition between the developing civilizations of medieval Europe and Byzantium.

As early as the time of Latin theologian Augustine of Hippo (d. 430 CE), Christians recognized that there was a Greek-speaking Eastern Church (*ecclesia orientalis*) and a Latin-speaking Western Church (*ecclesia occidentalis*). This division mirrored the third-century administrative division of the Roman empire into eastern and western halves. These differences in language and religious observances did not form a source of general controversy. Starting during the fourth century, however, sources of tension developed between the ecclesiastical leadership of the Roman Church and the new imperial capital of Constantinople. During the ecumenical councils of Nicaea (325) and Constantinople (381), the Church of Constantinople was recognized as being second in status only to Rome in the pentarchy (the five major sees of the ancient world, also including Antioch, Alexandria, and Jerusalem). The bishops of Rome rejected this change, which they saw as an illicit innovation in the ecclesiastical hierarchy that threatened Rome's theoretical claim to jurisdiction over the faithful.

Relations between the followers of Rome and Constantinople were further complicated by sporadic disputes over religious teachings, including debates about the nature of Christ (Arianism), the question of whether or not to ban religious icons (Iconoclasm), and a disagreement over the origins of the Holy Spirit (the Filioque Controversy). Although these sources of contention did not cause any deep or lasting divide between Latin and Greek Christians, they led members of both Churches to express their disappointment in one another. From the perspective of Rome, Constantinople was a source of heresy and prone to disobedience. From the perspective of Constantinople, Rome was attempting to impose its will upon the entire Church without regard for other sources of authority.

During the eighth and ninth centuries, political developments led to a reconfiguration in the

► ROME, CONSTANTINOPLE, AND THE MISSIONS TO BULGARIA IN THE NINTH CENTURY

Conflict between Latin and Greek Christians was evident in the late ninth century when competing missions in Bulgaria directed by Rome and Constantinople caused a confrontation over ecclesiastical jurisdiction and religious practices. In a letter to the Bulgarian king, Pope Nicholas I (d. 868) informed him that several of the religious observances mandated by the Greek clergy were unnecessary and ill-advised. The Greek emperor and the current Greek patriarch, Photius (d. 891), responded with their own accusations against Rome and its Latin followers. At the same time, Nicholas and Photius were already involved in a dispute over Photius's recent election as patriarch, which Nicholas had judged illegal. In response to this developing crisis, Nicholas appealed to his supporters among the nearby Franks for a defense of the church, "especially the part known to use the Latin language."

Around 868 a Frankish monk named Ratramnus of Corbie composed a tract titled *Against the Objections of the Greeks* in which he defended the teachings, observances, and authority of Rome. Ratramnus did not insist, however, that the Greeks

conform to the religious practices of the Latin churches. The leaders of the Greek Church and empire, according to Ratramnus, had themselves failed to recognize that the universal body of the faithful contained within it a great diversity of languages, habits, and rites. Quoting Augustine of Hippo, the Frankish monk declared that the church was like the "queen in her many-colored robes" (Ps. 45:14), adorned with variety and variation before Christ her king. This immediate dispute was settled by two councils held at Constantinople in 869–870 and in 879–880. Over the long term, the Bulgarian Church developed within the Greek Christian tradition.

relationship between Rome and Constantinople. The gradual disintegration of the western Roman empire and the growing Islamic dominance of the Mediterranean resulted in an increasingly tenuous sense of connection between the bishops of Rome and the imperial government of Constantinople. Searching for patrons, the Roman papacy forged a closer connection with the nascent polity of the Franks to their north, a mutual collusion that culminated in the reconstitution of the Western imperial authority under the Carolingian ruler Charles the Great (d. 814). This alliance between the Church in Rome and the Franks resulted in the persistent idea that there were two Christian empires, one in the East and one in the West. Over the long term, this political division intensified a mutual awareness among Latin and Greek churchmen of their religious differences.

Despite these historical episodes of contention, contemporaries on both sides continued to recognize the bonds of Christian fraternity that formed, in theory, the universal Church. Subse-

quent generations of Latin and Greek Christians received a dual inheritance from their predecessors, including examples of crisis and prejudice between the supporters of Rome and Constantinople but also an insistence that the two Christian peoples could and should resolve their periodic confrontations.

The Transition from Paganism to Christianity

Christianity did not succeed paganism easily or all at once. Decisive events and social forces shaped history over centuries of time. One famous event occurred on October 28, 312, CE, when the Roman emperor Constantine I fought the Battle of the Milvian Bridge. According to legend, he received a vision of the cross and a divine promise that he would triumph over his rival, Maxentius. Constantine, later dubbed “the Great,” did indeed find victory. The subsequent Edict of Milan in 313 officially ended all religious persecution and made the empire religiously neutral, but the emperor’s patronage of Christianity accelerated the shift from paganism to Christianity.

Before 313 Christianity grew only modestly. The pagan social order in the Mediterranean was already at least 2,000 years old and held great wealth and power. Wars, plagues, famines, population disruptions, and the resulting social upheaval of 300–475 CE destabilized this order, and Christianity offered a semblance of meaning and support in an increasingly chaotic Roman empire. Christianity thus grew more rapidly. Otherwise, Christianity likely would have remained a minor faith in a vast pluralistic religious ocean because pagan polytheism was central to the ruling hierarchy and tradition; religion and the established order reinforced each other.

To overcome hierarchy and tradition, Christianity required a powerful patron such as Constantine, and thus conversion offered opportunities in land and appointments. Christianity also introduced notions of spiritual equality, an afterlife in heaven, charity, self-sacrifice, and moral control for the common good, all of which likely appealed to oppressed groups, including slaves, women, and the poor.

Unfortunately, we do not really know what the common and oppressed people believed; there were no opinion polls, and they left no writings. Among intellectuals, debate raged. Against Christianity, Lucian of Samosata complained that the Christians accepted into their groups any person who desired to join them. Thus, any unscrupulous person could take advantage of them and acquire quick wealth by stealing from them and using them.

Lucian and other pagans saw Christians as fools who ignored reality and thus cared little for practical daily matters and willfully disregarded their own lives. More strongly, Galen (Claudius Galenus of Pergamum, 131–201 CE) complained that the Christians rejected the truth of the observable world, and their devotion to a capricious God made them unfit to live in civilized society. Porphyry of Tyros (232–304 CE) argues that Christians rejected logic in favor of blind faith, which in turn stands on belief that consists of spectacular but mythical stories. For Porphyry, Christianity lacked the two foundations that all truth requires: logic and history. Thus, its faith had no valid foundation; Christianity stood on nothing.

Other intellectuals supported Christianity. Tertullian (Quintus Septimius Florens Tertullianus, 155–230 CE) in his defense of the faith also defined many aspects of Christianity, including the concept of the Trinity. Many also countered Porphyry, including Eusebius of Caesarea, Apollinarius of Laodicea, Methodius of Olympus, and Macarius of Magnesia, but these texts are lost. The ruling class also increasingly embraced Christianity after Constantine, such that its character changed from grassroots collectivism to an institutional hierarchy resembling the hierarchy of the empire.

Yet a pagan champion arose in the form of Julian (Flavius Claudius Julianus, 331–363 CE). As emperor, Julian attempted to reverse Christian ascension to power and ever-increasing widespread popularity through a series of legal renderings and active political and economic promotion of paganism. However, Christianity had spread too fast and too far; a Christian majority arose in the eastern half of the empire sometime in the latter half of the 300s. Julian died in a field tent, mortally wounded at the Battle of Ctesiphon, the Persian capital. His friend and historian Ammianus Marcellinus recorded his final words as “Vicisti, Galilae,” or “You have conquered, Galilean,” in reference to Jesus. Never again would paganism have a champion against Christianity.

However, paganism did not simply die at that moment. Despite laws against sacrifices, seizures of idols by the state, and many other violent efforts to suppress and terrorize paganism, it survived unapologetically. Many communities

► CHRISTIAN COMPETITORS—THE EXAMPLE OF MITHRAISM

Many religions besides Christianity that increased in popularity during the tumultuous years 300–476 CE in the Roman empire promised salvation through a savior sent by God to redeem humanity. Among these was Mithraism, based on the figure of Mithra the bull slayer. The epithet suggests that Mithraism began as a local tribal belief, likely based on the life of an outstanding individual.

The earliest references to the Mithra cult date from 1380 BCE in a treaty between Subbiluliuma, king of the Hittites, and Mativaza, king of the Mitanni. With origins thus in Persia, Mithraism spread across Asia Minor and arrived in Rome sometime in the mid-first century CE.

As human civilization advanced and perception of the cosmos grew in size and complexity, the gods likewise changed from local tribal divinities to grander and more powerful deities. As Mithraism spread westward, Mithra evolved from a bull-slayer hero into a divine redeemer whose life now showed the path to salvation. Sacred sites remained in caves called grottos, the setting of Mithra's original bull sacrifice. Toward the end of the western Roman empire in 476 CE Mithraism closely resembled Christianity, with devotional rituals of redemption and seeking converts to serve the one God and fulfill his divine purpose.

Mithra sacrificing a bull as part of a Roman baptism ceremony, second century CE. (Jupiterimages)

—George Nels Lundskow

beyond the major cities in the late empire, Rome, Antioch, and Constantinople, refused to convert to Christianity. When the Byzantine emperor Justinian (527–565 CE) reconquered the southern half of the Italian peninsula, he discovered that the people had retained many pagan practices, including polytheism, and still celebrated many pagan holidays. Numerous pagan towns and communities survived well into the 800s CE, especially in Spain, rural Italy, and nearly all of North Africa. Boniface reports in 742 that the populace continued to observe numerous pagan feasts and festivals in St. Peter's Square in Rome, with singing, dancing, and ritualistic observances all on the traditional dates and following pagan customs.

Furthermore, recent evidence now shows that paganism actually survived, if diminished, throughout the Middle Ages in nearly all parts of

Europe, and Christianity blended with many traditional pagan and folk beliefs and practices, including animal husbandry and farming, herbology and medieval medicine, and trade guilds. People celebrated the solstices, equinoxes, and other festivals, perhaps into modern times. Pagan culture shaped Christianity from its beginnings as an ascetic cult and into the ostentatious pageantry and embrace of life by the time of the Renaissance, a rebirth of the ancient pagan arts and sciences, architecture, sculpture, and philosophy.

Even today influences remain, such as the Christmas tree and the yuletide, which refer to the pagan celebration of the Winter Solstice (December 22). The Easter Bunny and Easter eggs are pagan fertility symbols, and the word “Easter” derives from Ostara, the pagan celebration to the end of winter when the gods return from the underworld. Halloween is the pagan celebra-

tion of Samhain from which the Day of the Dead in Mexico is derived.

Early Medieval Orthodox Christianity

Three factors early in Orthodox Christianity provide its distinguishing marks. These are the doctrinal controversies of the fourth and fifth centuries, the relationship of the emperor to the Church, and an ecclesiology (theological doctrine) that emphasized collegiality among the bishops. The first factor generated an elaborate Christian theology of the Trinity. The second created a political theology whose effects would be felt for centuries, and the third resulted in the system of patriarchates in Orthodox Christianity.

In 312 CE Constantine attributed victory over his last enemy, Maxentius, to the Christian God. The Edict of Milan (313) from Licinius, coruler in the East, and Constantine legalized Christianity, and Constantine's support of the new faith led to his being regarded as the first Christian emperor. Critical to understanding Orthodox Christianity is Constantine's concern for a unified Church.

The great doctrinal controversy of Constantine's reign was Arianism, named for Arius, a presbyter of Alexandria. Central to Alexandrian theology was the Logos, the Word of God that became flesh (Incarnation) and rational principle governing the universe. Arius argued that the Logos was subordinate and less fully divine than the Father, a common but not universal position then. The resulting controversy bitterly divided the Church. Meanwhile, Constantine defeated Licinius in 324 and saw a unified Christian Church as central to securing sole rule over the empire. In 325 he brought the sparring bishops to Nicaea, close to his newly built capital, Constantinople. The Nicene Creed declared both Father and Son fully and equally divine, or *homoousios* ("of the same substance"). The emperor had taken a direct hand in Church affairs. His involvement continued when the harmony suggested by the successful council never materialized, and Constantine exiled uncooperative bishops. Through the fourth and fifth centuries, doctrinal disagreement coupled with political action became commonplace, the latter based on a theory of kingship that placed emperor and Logos in parallel functions. The Logos piloted the universe, and the emperor guided the affairs of the world. The theory depicted a devout Christian ruler who fulfilled his duty at Nicaea and throughout his reign.

Post-Nicene theology wrestled with the problem of attributing a full humanity to Jesus Christ rather than one compromised by divine attributes. The Cappadocian fathers Basil the Great, Gregory of Nazianzus, and Gregory of Nyssa were foremost among the fourth-century theologians who addressed these questions. They insisted on a Redeemer both divine and human against such theologians as Apollinarius of Laodicea, who made little room for the savior's humanity. The Council of Chalcedon in 451 dogmatically

THEOTOKOS—GOD’S MOTHER

Little in Orthodoxy is more easily recognized than the iconic representation of the Virgin Mary, Christ child in arms. She is Mother of God, or God-bearer, Theotokos. Early orthodoxy was divided over the title, however. Theologians from Antioch objected that Theotokos, used for years by Alexandrians, compromised the full humanity of the redeemer. Nestorius, patriarch of Constantinople, opposed Cyril, bishop of Alexandria. The Council of Ephesus in 431 allowed the use of the honorific to the Virgin primarily to guard against a diminished understanding of the full divinity of Christ.

—Gerald S. Vigna

defined Jesus Christ as possessing two complete unmingled natures, divine and human.

The fifth century also saw increased mysticism in Orthodoxy. Influenced by platonic dualism, theologians postulated the inadequacy of human comprehension in understanding the divine and thus described God in negative, or apophatic, terms (e.g., unknowable, or immortal). Yet these mystics also sought spiritual union with God through prayer and contemplation. Fifth-century writings erroneously attributed to Dionysius the Areopagite (Pseudo-Dionysius) influenced East and West in their description of a God intellectually unknowable but experientially accessible. Seventh-century Maximus the Confessor wrote an influential commentary on these that ensured their place in Orthodox thought.

Orthodox theology emphasizes the importance of the Incarnation and thus the value of the material world as a medium through which God is revealed. Consequently, the veneration of images (icons) holds an important place in Orthodoxy. In the eighth century, however, theological discomfort with the material world and distrust of graven images raised the issue of icons’ legitimacy. The Iconoclastic Controversy also showed the intimate connection between Church and throne. Emperor Leo III, attempting to control the Church and centralize the state, forbade the worship of images in 725. His decree caused a religious revolt and had no backing from the papacy. The Second Council of Nicaea, the last of the Seven Ecumenical Coun-

cils, met in 787 and fervently defended the use of images.

Earlier speculation on the Trinity had left one question unanswered: the manner of the Holy Spirit’s generation within the Godhead. The Western churches had begun in the sixth century to assert that the Holy Spirit proceeded from the Father “and the Son” (*filioque*); they did this perhaps to preserve the full divinity of the Son against late Arian ideas. In the Filioque Controversy, the East complained that the Western idea raised questions about the unity of the Godhead. The question of the primacy of the bishop of Rome over the Eastern churches, at issue as early as the second century, again surfaced. Pope Nicholas I’s intervention in 863 into the conflict between Ignatius and Photius, competing patriarchs of Constantinople enjoying alternating periods of royal support, was ignored in the East. Ignatius had been exiled by the emperor Michael III, and the pope declared Ignatius the rightful patriarch. With Nicholas’s claim to universal ecclesiastical jurisdiction unheeded, Photius launched an attack against the filioque and branded Nicholas a heretic in 867. The controversy flared again early in the eleventh century when the papacy inserted filioque into the creed. The East’s insistence that the creed could be changed only by a Church council highlighted the critical ecclesiological difference between East and West.

The Filioque Controversy came to a head because of the ninth-century missionary journeys of Eastern and Western Christians to the Slavs. The East’s apostles to the Slavs were two brothers, Cyril and Methodius. To reach these pagan tribes, they created an alphabet, the Cyrillic alphabet, that enabled them to bring the Scriptures to their churches. From the West, German missionaries brought both Gospel and filioque. They clashed in Moravia, and the brothers appealed to Pope Hadrian successfully but ultimately to no avail, as German missionaries expelled their followers from Moravia after the brothers’ deaths. Nonetheless, the acculturating methods of Cyril and Methodius were successful in Bulgaria, Serbia, and other Slavic regions through the conversion of Russia in the tenth century. East and West differed doctrinally over the filioque and ecclesologically over the primacy of the bishop of Rome. By 1054, with mutual excommunications, the rift had become nearly irreparable. With the

thirteenth-century sack of Constantinople by the crusaders, it was irreparable.

The Orthodox Church—Clergy, Feasts, and Practices

Orthodox Christian worship is a study in the contrast between the timeless and the historical. The rites that have become Orthodox worship and liturgy would have been impossible without the legalization of the religion in the later Roman empire and the ensuing church-state relationship that both built churches and saw imperial intervention into doctrinal controversies for centuries after. Elements of mysticism unite Orthodox theology and worship. For believers its prayer, sacramental rituals, and icons reflect heavenly eternity and humanity's participation in it. In contrast to the Latin West, Eastern Orthodoxy spent less time wrestling theologically with the mysteries of Christian faith and instead prayed them in word and action. A later theologian would summarize this harmony as *lex orandi lex credendi*, or "That which is prayed is that which is believed." These religious underpinnings led to a strong emphasis on tradition and have resulted in a genuine constancy in worship within the broader envelope of historical change.

Prior to the fourth century, Christianity held its worship in private homes or hidden places. Much of what became the liturgy began to develop during this time. With state sponsorship

of the church, grand spaces for public worship were built. In addition, the doctrinal controversies that raged through the fourth and fifth centuries had implications for worship. Consequently, two great theologians of the time, Basil the Great and John Chrysostom, turned their attention to it, and the two prominent liturgies in the Orthodox Church today have traditionally been attributed to them. The Liturgy of St. Basil is used in the contemporary Orthodox Church on great feast days such as Easter and Christmas and also Sundays during Lent as well as other times. Reliable tradition ascribes it to Basil. That of St. John Chrysostom is attributed with much less certainty to him. It is the liturgy used for most of the year and, like that of Basil, saw translation into the many languages of Orthodoxy. The Barberini Codex from the eighth century describes the Divine Liturgy. It consisted of two parts, the Liturgy of the Catechumens and the Liturgy of the Faithful. The first opened with a procession by the bishop and the worshippers, followed by several Scripture readings. Only the baptized could remain for the Liturgy of the Faithful. This began simply enough before the fourth century but with the construction of great churches such as Hagia Sophia grew into the Great Entrance. There followed the Kiss of Peace and the creed, the Eucharistic prayers, and then the distribution of communion.

Orthodoxy organizes its worship according to an annual calendar that begins again every September 1. The preeminent event in the calendar is Easter. The Twelve Great Feasts follow in importance. Orthodox Easter celebrates the resurrection of Jesus Christ. This was and remains the day for initiation of new Christians through the sacraments of Baptism, Chrismation, and Eucharist. The mystical element in Orthodox spirituality is apparent in its Twelve Great Feasts. Eight of these celebrate events in the life of Christ; four are dedicated to Mary in recognition of her role as Theotokos, or bearer of the Christ. Prominent among them is the feast of the Transfiguration of Christ (August 6), which commemorates the episode in the Gospels where Jesus Christ manifested his divine glory to Peter, James, and John on Mount Tabor. This divine glory will someday be humanity's since Orthodoxy's idea of salvation includes *theosis*, or divinization. In addition to the Twelve Great

► THE CHANGING TRADITION OF LITURGY

The Eastern Orthodox Divine Liturgy saw development from the sixth through tenth centuries. The liturgy consisted of two parts, the Liturgy of the Catechumens and the Liturgy of the Faithful. The first opened with a procession by the bishop and the worshippers. They chanted the Trisagion (Greek for “three” and “holy”). Although the origins of this chant may go back earlier, following the principle of *lex orandi lex credendi*, it was intended to refute the heretical Monophysite Christology. Central to the Liturgy of the Catechumens were four biblical readings, one from the Old Testament, a psalm, a New Testament reading (an epistle), and one from a Gospel. The Liturgy of the Faithful began with the presentation of the gifts (bread and wine) followed by the Kiss of Peace and the creed, this last introduced by the Monophysites to demonstrate their orthodoxy. Then came the Eucharistic prayers or anaphoras over the bread and wine and the distribution of communion. By the ninth century some changes had occurred. For example, the Trisagion yielded its place to a psalm that varied according to the feast celebrated and moved to a later spot. Because of this shift the Great Entrance no longer occurred, and the Little Entrance, which included only clergy, arose. The Liturgy of the Faithful increasingly allowed for private prayers by the priest rather than the entire congregation, much like in the West.

—Gerald S. Vigna

Feasts, there also are several lesser feasts and four important periods of fasting, the most significant of which is Lent.

Orthodoxy's sacramental rituals also reflect a religious imagination that leads to a mystical view of heaven and earth. The Barberini manuscripts provide our oldest complete texts of the Easter baptismal rite. This rite included exorcisms, renunciations of Satan, and the recitation of the Nicene Creed before the blessing of the baptismal water and the catechumen's immersion into it. Orthodoxy has always confirmed the newly baptized as part of this rite. Eucharist unites the church with Christ as the Body of Christ and believers with one another. Orthodoxy maintains that Christ is present in the bread and wine and, unlike the medieval West,

did not struggle first with Platonic and then Aristotelian explanations but instead believed what was prayed in its liturgy. Of the remaining sacraments, Holy Orders deserves brief attention. There are three major orders of clergy: deacon, priest, and bishop. A significant distinction in Orthodoxy that seems to date from the sixth century exists between married and celibate clergy, or white clergy and black (monastic) clergy. The decision to marry must be made before a man is ordained deacon; only black clergy may be ordained bishops. Because Orthodoxy emphasizes collegiality, bishops make decisions in Ecumenical Councils. In fact, one reason for the schism between Christian East and West was the disagreement over the jurisdictional role of the bishop of Rome over the entire church, a role that grew increasingly important in the West during this period.

The mystical understanding also explains Orthodoxy's devotion to icons, which Orthodoxy sees as reflections of heavenly reality. Through icons, the saints are available to Orthodox as fellow members of the worshipping church. In the eighth century when theological discomfort with the material world and distrust of graven images raised the issue of icons' legitimacy, the Iconoclastic Controversy again showed the intimate connection between church and throne through the actions of Emperor Leo III. Whether in public prayer or private devotion, from liturgy to iconic veneration, Orthodoxy emphasized the central principle of *lex orandi, lex credendi*; had a mystical element; and was affected by decisions of the state.

The Role of the Catholic Church in Early Medieval West European Civilization

The Catholic Church played a crucial role in the early medieval period by offering a unifying culture and ideology to western Europe as the Roman empire collapsed. In the early medieval period, the Church suffered like many of the other Roman institutions but proved resilient in its ability to survive. As new kingdoms and political institutions arose in western Europe, the Church provided a unifying ideal and vision that would become Christendom in the high Middle Ages. The pope in Rome was nothing like later, more powerful popes. He was still just the local bishop of Rome with little power even within Rome itself. However, his respect and prestige were tremendous. As the Roman empire disintegrated in the West, Pope Gregory the Great (540–604) set the tone for future medieval popes. He took on secular duties as necessary, not because he wanted the power or felt that it was his job but because he was the first citizen of Rome, and there was no one else to fulfill the role in the absence of imperial authorities. He negotiated and corresponded with rulers and leaders throughout the West to protect Church interests, and he sent missions to pagan peoples. Just as the empire lost territory, so too did the Church. When Britain was overrun by the pagan Saxons and Jutes (mid-fifth century), Christianity nearly died out on the island. However, the Church was able to send missionaries who did not depend on military invasions or politics. Celtic missionaries arrived from Ireland, Cornwall, Wales, and Scotland. Pope Gregory sent Augustine to become the first archbishop of Canterbury in 597. In the next two centuries a thriving Anglo-Saxon Christianity would flourish, and the English Church would send missionaries to the continent.

However, early medieval popes such as Gregory had very little real power over the Church outside the city of Rome. The pope's prestige made him the paramount bishop in the West, and all other bishops deferred to the pope in matters of doctrine or even liturgy, but such questions rarely arose. In the administration of their dioceses, most bishops reported to the local Germanic ruler, the ruler who had appointed him.

➤ CAROLINGIAN RENAISSANCE

The Carolingian Renaissance worked closely with the Church to revive learning in the West. Cathedral schools in cities imitated the palace school of Aachen, and the groundwork for later medieval learning and universities was laid. Monastic schools also played a role in educating nobility and future clergy. Although the Carolingian world collapsed into civil war, the monasteries kept the memory and ideals of Christian learning alive. Cluny proved to be the monastery wealthy enough and sufficiently independent enough to lead a new revival. It founded daughter houses throughout western Europe to educate future Church leaders and to demand ecclesial independence.

—Benjamin de Lee

Throughout the West, monasteries, often just individual hermits or small monastic foundations, were models of piety to local people. They were also repositories of learning. The most important monastery of the early medieval period was the monastery founded by Benedict of Nursia (ca. 480–545) at Monte Cassino in 529; Benedict's *Rule* was used throughout the West as a guide to govern monasteries. Monasteries were often founded or endowed by local rulers and nobility. The local ruler would even appoint the abbot. The monasteries provided education for nobles' sons and contributed to local economic life. In spite of decline and fragmentation, the Church, through its episcopacy and monasteries, was still able to keep the embers of classical learning burning and to hold up an ideal of European Christianity.

Many of the Germanic tribes such as the Goths, Visigoths, and Ostrogoths that had brought about the collapse of the Roman empire were already Christian, albeit Arian Christians. Gradually these all came into the fold of Catholic Christianity. The Franks were perhaps the strongest holdout of Germanic paganism, but Clovis I (481–511) embraced Catholic Christianity and encouraged its spread. Thus, even as the Roman empire collapsed, more and more Germanic tribes embraced a Christian ideology that was centered on Rome and rooted in Latin language and learning. Even the fierce Vikings of Scandinavia would

be converted to Christianity in the eleventh century, and they, too, would become a part of a European-wide Roman Catholic culture.

Charlemagne (742–814) typifies the incorporation of the Franks into Roman Catholic Christian ideology. He conquered and unified most of western Europe. In 800 he was famously crowned emperor of the Romans in Rome by Pope Leo III on Christmas day. Charlemagne encouraged Latin learning and most importantly Roman Catholicism, which he saw as a unifying agent in his empire. Indeed, he saw it as his duty to protect and promote the Church. Charlemagne protected the pope and sent missionaries into northern and eastern Europe.

The Catholic Church thrived under Charlemagne's patronage. It became very much a part of Carolingian state and culture, and later German and Frankish rulers saw it as their duty to protect and govern the Church. The Investiture controversy has its roots in the Carolingian period, when Frankish nobles and rulers saw it as their duty and right to appoint Church clergy, from the local parish priest to archbishops.

The interference of local nobles in Church affairs would provoke the Cluniac Reforms, named for the Cluniac monastery, founded in 910 by William of Aquitaine. The Cluniac reformers stressed the complete independence of the Church, especially monastic institutions, and they emphasized clerical education and celibacy. The reforms would become popular among clergy throughout the West. While conflict with rulers was inevitable, the Church ultimately won. By the year 1000 the Church had survived numerous invasions by peoples whom it ultimately converted, and it had achieved enough independence and centralization to pursue the reforms of the high Middle Ages.

Religion in Georgia

Georgia, in the Caucasus, is one of the oldest Christian nations in the world.

Georgia in the year 300 CE enjoyed a level of religious diversity common throughout much of the Near East and eastern Mediterranean at that time. Due to its proximity to Persia, a local form of Zoroastrianism flourished in eastern Georgia (Kartli, or Iberia), while in western Georgia (variously known as Colchis, Egrisi, or Lazica), long exposed to Greco-Roman influences, various pagan deities were worshipped. Jewish communities had long thrived in Georgia, particularly in Mtskheta, the capital of Kartli. Archaeological evidence also shows that early followers of Christianity were present in western Georgia by the year 200 CE, and most likely the Jewish community in Mtskheta included followers of the Jesus movement.

This was the setting, in about 337, for the conversion of King Mirian of Kartli to Christianity by St. Nino, a humble woman from Cappadocia (present-day Turkey). Together with such states as Armenia and Ethiopia, which also adopted the new religion in the fourth century, the Christianization of Georgia thus followed a Constantinian model whereby rulers were targeted for conversion. For Georgia, the adoption of Christianity was a pivotal moment. For the first time in its history the country looked toward the West.

Though Georgian Christianity was very much part of a wider Pan-Caucasian missionary effort, the beginnings of a national church can be discerned in the period up to the Arab invasions of the seventh century. By the middle of the fifth century a network of episcopal sees, with Mtskheta at its apex, had been established across eastern and western Georgia. To propagate the new faith, an alphabet was devised for the Georgian tongue (in much the same way as a local script was invented to spread Christianity

➤ JVARI CHURCH

The first Georgian Christians were confronted with the challenge of creating sacred spaces that accommodated both the spiritual and liturgical requirements of their new faith. The earliest churches in Georgia employ the Greco-Roman basilica model, a long, rectangular-shaped structure divided lengthwise into three aisles, each separated by colonnades or, in some cases, walls. Although the basilica model provided the basic template for the first two centuries of Georgian church building, its linear composition differed sharply in ethos and shape from the circular plans that characterized domestic dwellings. The rigidity of the basilica design may also have provided a less than harmonious setting for liturgical chant, which to this day plays an important role in Georgian services.

These factors were likely the impetus for the development of a new architectural style: domed structures in which a central cupola is surrounded by four apses of approximately equal size (making a cruciform). In the earliest examples of tetraconch (four-apsed) churches, the conches protrude somewhat awkwardly from the base of the cupola, but in the next decades the technique would be refined. The magnificent early-seventh-century Church of Jvari (Church of the Holy Cross), built on a hill overlooking Mtskheta where King Mirian had erected a large cross after his conversion in the fourth century, represents the culmination of these

Jvari Church above the city of Mtskheta in present-day Georgia. The church was built between 586 and 605 on the site where, according to legend, Saint Nino converted the Pagan population to Christianity. (Shutterstock)

efforts. The interplay of design elements—cupola, conches, outer walls—is brought into a single integrated ensemble. The overall effect is to create an atmosphere that is organic and unitary. Although basilica designs did not entirely disappear from Georgia, Jvari marks a new era, foreshadowing the monumental cathedrals of the tenth through thirteenth centuries that would characterize Georgia's golden age.

—Charles Cavaliere

in neighboring Armenia), and biblical, patristic, and liturgical texts were translated, primarily from the Greek but also from Assyrian, Aramaic, and Armenian. Sometime late in the fifth century the earliest known example of Georgian literature appeared: *The Passion of St. Shushaniki*, the story of an Armenian princess put to death by her husband for refusing to convert to Zoroastrianism. Other hagiographies would follow in the next centuries.

During this formative period, a Georgian style of ecclesiastical architecture developed. The first churches in Georgia were constructed using the Roman/Byzantine basilica plan, but by 600 a uniquely Georgian idiom had emerged: the domed tetraconch church. Another important development is the appearance of a native

hymnography—liturgical chant—that fused biblical, Byzantine, and pre-Christian poetry into harmonious, polyphonic compositions. Still an integral part of church services today, these hymns (known as *galoba*) form an unbroken chain of cultural and artistic transmission from antiquity to the present.

Up until the eleventh century Georgian Christianity looked south, toward Syria, the Levant, and Palestine, for spiritual inspiration and ecclesiastical guidance. The liturgy in Georgia followed the Jerusalem rite until about the year 1000. Monasticism was the fulcrum for Georgia's relations with the Near East. Georgian monks were active in monasteries in Antioch, Jerusalem (where the oldest inscription written in Georgian, dated to 430, is located), and later at St.

Katherine's in Sinai. Numerous Georgian manuscripts survive from these centers. Georgia itself (or more specifically, Kartli) was colonized by a group of ascetics known as the Thirteen Syrian Fathers in the first half of the sixth century. Important monastic communities were established by Shio Mghvimeli near Mtskheta and by David Garesjeli in the eastern desert.

It is important to note that up until the seventh century Georgia, along with neighboring Armenia, was monophysite, that is, it held the doctrine of the one and single nature of Christ. This conflicted with the teachings promulgated by the imperial church council of Chalcedon in 451. But in 607, at a time when Georgia looked increasingly to the Byzantine empire for protection from Sassanid Persia, Georgia broke with the Armenians and embraced diophysitism (the doctrine that holds that Christ's nature is both wholly human and wholly divine).

Georgia's growing links with Constantinople were temporarily disrupted in 645 when Arab armies invaded. By 655 all of Kartli had become an Arab emirate. Though the emirs interfered little with Georgian culture, Muslim suzerainty caused many Kartvelian nobles and religious elites to relocate to the southwest, to the regions of Tao-Klarjeti and Shavsheti, where far from the Arab metropole based in Tbilisi (which replaced Mtskheta in the fifth century as the capital of Georgia), Georgian Christianity took on renewed vigor. Unimpeded access to Byzantine ideas and practices led, most notably, to the replacement of the Jerusalem rite with the Constantinopolitan early in the new millennium. From the ninth century, important new churches were founded in both eastern and western Georgia: Shatberdi, Tbeti, and Oshki (all in present-day Turkey); Bagrat (Kutaisi); Samtavisi (Kartli); Nikortsminda (Racha); Svetitskhoveli (Mtskheta); and Alaverdi (Kakheti). The size and scale of these churches were unprecedented and surpassed anything being built in Byzantium at that time. They spurred a dramatic increase in the production of religious literature: gospels, exegetical works, church music, philosophical tracts, and more. Georgian culture was by no means parochial. At the turn of the millennium Georgians were increasingly present at Constantinople and other foci of eastern Christianity. The monastery of Iveron ("of

the Georgians") was founded at Mount Athos in northern Greece in the tenth century and became an important literary center.

As a sense of national identity emerged, two of the first histories were composed sometime in the ninth or tenth century, both dealing with the spread of Georgian Christianity: *The Conversion of Kartli* and its more elaborate counterpart, *The Life of St. Nino* (earlier redactions can be traced to the seventh century). Though these histories are concerned with events from the fourth century, their outlook reflects the vigor and confidence of a national, indisputably Georgian, church. Further evidence of the church's power is supported by the change in title of the chief prelate from "catholicos" (a position somewhat equivalent to archbishop) to "patriarch" at some point in the eleventh century. The nationalistic tone of this new designation is unmistakable.

At the beginning of the new millennium the Georgian church had never been more wealthy or powerful. Aided by the growing might of the Bagratid kings, who first seized power in Tao-Klarjeti in 813 and who strenuously sought to unify all of Georgia under a single monarch (a goal realized in 1008), a true national church took shape, one that encompassed both east and west Georgia as well as lands inhabited by many non-Georgians. The next two centuries would be a golden age for Georgian Christianity.

■ Introduction: Early Islam

Islam was the youngest of the major monotheistic religions to emerge in the first millennium CE. The Islamic religion claims a pedigree stemming from Christianity and Judaism. When Islam was first proclaimed in Arabia in the early seventh century, it entered a religious milieu dominated by Christianity and Zoroastrianism, both intolerant faiths. Islam from the beginning subscribed to the basic eschatology of dualistic Western religions: that the most important narrative is that of the struggle between the forces of good and evil, that the powers of good will win, and that there will be a day of judgment when the good will be rewarded with Paradise and the evil punished.

Islam establishes no priesthood as intermediaries between the laity and the deity. Islam insists that all believers are equal before the deity, without income, national, or racial distinctions.

Islam started as a conquering politico-religious movement and rapidly built an empire that straddled western Eurasia from Iberia's Atlantic coast to the western confines of Hindu and Buddhist India. In that vast empire, the Muslims created a civilization synthesized from the civilizations they conquered and those with which they came in contact. Despite frequent civil wars (*fitna*) and the very serious Sunni-Shia schism, the Muslim world (Dar al-Islam) became the world's leading community of faith by the end of the first millennium CE.

After the initial conquests, Islam rapidly gained converts, partly, it is said, because Islam taught a less complex and easier to understand theology with its uncompromising insistence on monotheism than either its Christian opponents, with their constant debates concerning the divinity of Jesus and the nature of the Trinity, or its Zoroastrian antagonists, with their more complicated cosmology. In the lands they conquered, the Muslims rarely tried to convert the Christian or Zoroastrian population en masse, though they did insist that their non-Muslim subjects (*dhimmi*) accept a secondary role in the new state and pay a special tax. In most Muslim lands, large Christian or Zoroastrian populations persisted for centuries.

After a century of an almost unbroken series of victories, the Muslim Arab career of conquest came to an end. Arab Muslim armies failed to take Constantinople in the siege of 717–718, and Arab Muslim forces were defeated at climactic battles in France and in India in the 730s. Significant expansion of Muslim states would not be resumed until after 1000 CE.

Nevertheless, by the year 1000, Islam probably had the most followers of any religion in the world. It was the principal religious expression of what may have been then the most dynamic and creative civilization on the globe.

—Wilfred J. Bisson

The Founding of the Islamic Religion, circa 610–680 CE

Although Islam is some 1,400 years old, the myths, personalities, events, and controversies of the period from around 610 to 680 are fundamental to understanding the religion's subsequent development into what it is today. With the appearance of its Prophet Muhammad came also the mainstay of Islamic religious doctrine, the Quran. Furthermore, the events after Muhammad's death engendered the two main denominations of Islam, Sunni and Shia. The Islamic religion has humble origins in Mecca, a city on the western Arabian Peninsula.

Prior to Islam, Arabia was shared by different Christian, Jewish, and, predominantly, polytheist religious communities. Although little can be known for certain about pre-Islam Arab polytheists, it is known that there were several hundred deities, and they believed that the world was populated by demons (*jinn*) that had to be appeased or defeated by magic. Mecca itself was a major center of worship, housing the Kaaba, the holiest site for the polytheist Arabs. A great black cubic structure around which were placed effigies of various gods to whom the Arabs would pray and make sacrifices, the Kaaba was also a major place of pilgrimage. However, although Mecca was a center of worship for pre-Islamic polytheism, it was also a natural place for the genesis of monotheist Islam. It was a cosmopolitan city populated by Jews and Christians

The Kaaba is a shrine that houses the Black Stone of Mecca, the focal point for Muslim prayer and final destination for pilgrims to Mecca. (Ayazad/Shutterstock)

in addition to polytheists and was brought into frequent contact with diverse religious ideas via trade and missionaries. As a center of commerce, Mecca itself was undergoing major social change in the sixth and seventh centuries that helped facilitate the rise of Islam. While the merchant class prospered, disparities in wealth as a whole increased, resulting in growing dissatisfaction with the prevailing social order and helping to create receptiveness for Islam. Although Islam is an outgrowth of this particular historical context, it is referred to by Muslims as the *jabilliyah* (“time of ignorance”) before Islam.

Islam is said to have its origins in 610 when Muhammad, a Meccan merchant, began receiving revelations from the angel Gabriel, who was delivering to him the direct word of God (Allah). These revelations, which Muhammad received until his death in 632, formed the Quran, Islam’s holy text. In the first years in Mecca, the revelations dealt primarily with the fundamentals of the religion, focusing on the monotheistic nature of the single all powerful, just God and the apocalypse to come, when everyone would pass before God, who would judge them based on their piety. It also focused on prophetic narratives. Muhammad was told that God’s message, Islam, had been received by various communities in the past through prophets of their own, many of whom are familiar in Christianity and

Judaism, such as Moses, David, Abraham, Noah, Jesus, and others. Included also were prophets unique to pre-Islamic Arabia. Muhammad was told that he was the final prophet in this long line and was sent to deliver the Arabs from sin and to rescue them from polytheism. At this time, Christians, Jews, and polytheists were all intended for Muhammad’s message; it was not yet clear that Islam was to become its own separate religion. Parts of these original messages display certain parallels with Judaism and Christianity. The concept of a prophet sent to save a chosen people, for example, is consonant with Judaism, and Muhammad’s articulations of the last judgment are similar to Christian tradition.

This new message represented a profound challenge to the predominating western Arabian worldview. Furthermore, as the new cult gained converts and status, the Meccan elites who had traditionally wielded control over religious affairs felt threatened. Thus, in 622 Muhammad and his Meccan followers were forced to migrate about 200 miles north to Medina. This event, known as the *hijra* (migration), is one of the defining moments in Islam. Its significance is such that the Muslim calendar begins here, in 622, at year 1.

While in Medina, revelations of the Quran continued to come to Muhammad, but they generally underwent a change of emphasis, reflecting the new reality in which Muhammad had found himself. Now, he was tasked with building an Islamic community (*umma*) and bolstering the legitimacy of his prophethood and leadership. Broadly speaking, the Quran now came to focus on legislative topics dealing with rites, rituals, laws, ethics, and other aspects necessary for building a faith-based polity and identity. Thus, the Quran now asserted that Muhammad was to found an entirely new religion, specifically distinct from Christianity and Judaism, and by doing so restore true monotheism. Also at this time were revealed the Five Pillars of Islam, five obligations for Muslims that in particular distinguish Islam from the other monotheistic faiths: *salat* (ritual prayer five times daily, facing Mecca), *zakat* (almsgiving to the poor), *hajj* (pilgrimage to Mecca for those who are able), *sawm* (fasting during the holy month of Ramadan), and *shahada* (testifying that there is only one God and that Muhammad

is his Prophet). At the same time, the rules governing the relationship between Muslims and Christians and Jews were revealed. People of the Book, those who believed in one God, in revelation, and in scripture, were to be allowed to practice their faiths as long as they accepted the Islamic political system and paid their taxes.

By 630, after a long process of conversion and winning over allies, Muhammad and his followers were able to enter Mecca without resistance. The Kaaba was purged of its polytheistic idols and relics and is now Islam's holiest site and still the destination for annual pilgrimage. Muhammad died soon afterward in 632. By the time of his death, the Quran, the foundation of Islamic religious life, had been revealed, and indeed the text has changed little if at all over the last 1,400 years. However, the Quran did not set forth any sort of criteria for selecting a successor (caliph) to Muhammad. Although it had been made very clear that Muhammad was the final prophet, the young Muslim community was still in need of a leader, and the next 50 years were predominantly concerned with working this out. If the years 610–632 are important because during this time the tenants of the Islamic faith were established, the years 632–680 are important because the events that occurred during this time gave birth to the two major denominations of the Islamic faith, Shia and Sunnism.

After Muhammad's death, there was disagreement as to who should succeed him as leader of the *umma*. Certain Muslims thought that the Quran had mandated that a member of the family of the Prophet should guide the new community and placed their support behind Ali, who was Muhammad's cousin, son-in-law, and an early convert. However, from 632 to 656 Ali was passed by three times in favor of other pious Muslims: Abu Bakr (d. 634), Umar (d. 644), and Uthman (d. 656). Ali then reigned as caliph until his assassination in 661. Following his assassination, his rival Muawiyah claimed the title of caliph and established the Umayyad dynasty, ruling from Damascus. In the East, particularly in present-day Iraq, supporters of the family of Ali refused to recognize Umayyad authority. In 680 Husayn, one of Ali's sons, rose up against the Umayyad dynasty and was slain at Karbala in Iraq.

These events engendered permanent divisions in the Islamic community. The Sunnis accept Muawiyah and those who came before and after him, idealizing the first four caliphs as the *rashidun* ("rightly guided") caliphs for their piety as Muslims. The Shia, representing now about 10 percent of Muslims worldwide, maintain that only blood heirs of Ali could lead the *umma*, with the largest subgroup claiming that one day a messianic descendant of the line of Ali called the Mahdi will appear toward the end of time to spread peace throughout the world.

Teaching and Practice of Early Islam

The teachings and practices of early Islam represent both change and continuity with pre-Islamic religious belief in Arabia. The Quran, the holy book of Islam that Muslims believe to be the direct word of God as revealed to the Prophet Muhammad during 610–632 CE, put forward the essential tenants of Islam that represent the core of Muhammad's message. At the same time, it was a blueprint for creating a new society based around a shared faith. It at once draws from and Islamicizes a great deal from the cosmopolitan array of Jewish, Christian, and polytheistic religious faiths found in pre-Islamic Arabia and also introduces new ideas that would have seemed radical at the time.

One recurring message is the oneness of God, or God as the sole omniscient and omnipresent

creator, in contradistinction to the polytheism that characterized much religious practice in pre-Islamic Arabia. Another major theme is a concern with Judgment Day and the hereafter. Mankind, the pinnacle of God's creation, is given the choice of whether or not to heed the call to God's religion and follow his teachings, and whether or not one passes this test determines if one goes to heaven or hell. The Quran also contains a great deal of prophetic narratives, or stories of how God had revealed the message of Islam to outstanding men in other societies such as Jesus, Moses, Joseph, etc., who are descended from the Judeo-Christian tradition, as well as other prophets who were natives of Arabia. Muhammad was to be the final prophet before Judgment Day. The thread unifying all of these themes is a strong emphasis on the need to be pious, to obey and fear God. The pervasiveness and vigor of this aspect of the Quran suggests that Islam began as a movement of militant piety.

Besides the message of God's oneness, the warnings of Judgment Day to come, the narratives of past prophets, and the exhortations to piety, the Quran was also an instruction guide for the practice of the religion. Much of these teachings of early Islam were instrumental in creating a communal identity for Muslims as a distinct, cohesive community (*umma*) bound together by common belief over the tribal ties that underpinned pre-Islamic communal identity. The Five Pillars of Islam serve as a case in point. Revealed to Muhammad as a set of obligations incumbent upon Muslims, the Five Pillars form the cornerstone of Islamic practice. Professing Islam (*shahada*), or uttering "I bear witness that there is no god but God, and that Muhammad is His Prophet," grants one entrance into the *umma* and also demonstrates that one accepts the belief in a single God rather than multiple gods (thus distinguishing it from polytheism) and the belief in Muhammad as Prophet (thus distinguishing it from Judaism and Christianity). Almsgiving (*zakat*) was a cornerstone of social justice and requires Muslims who are financially able to donate 2.5 percent of their net worth to charity. Fasting (*sawm*), which had also been a practice in Judaism and Christianity, requires that Muslims who are able fast during

the holy month of Ramadan. Ritual prayer (*salat*) is arguably the most important outward act of devotion. Interpreted in most instances as five prayers daily at fixed times, it could be performed alone or in a group of people of any size. Finally, Muslims who are physically and financially able are required to make the annual pilgrimage (*hajj*) to Mecca, Islam's holiest city. Consisting of a number of rituals performed in and around the city of Mecca and adapted from the pre-Islamic practice of pilgrimage, performing the *hajj* is perhaps the greatest act of devotion that one could perform and, like congregational prayer, is a highly public communal act of faith that drew Muslims together and helped cement their identity as a unique community.

Also within the Quran are numerous passages regulating social relations among Muslims. Along with the rites and rituals, these regulations played a key role in cementing the young community and represent both continuity and change with pre-Islamic practices. Concerning marriage, for example, the Quran has much to say. Marriage in Islam is a civil contract between two adults, with husband and wife as equal partners before God. A dowry is paid to the bride by the groom and becomes her personal property, and in financial matters she retains control of her own property and assets. Divorce was highly discouraged, but in the event of a divorce women were free to initiate the proceedings. The pre-Islamic practice of polygamy remained permissible, but the Quran sought to mitigate it by stipulating that a husband must be able to treat all of his wives equally and by limiting him to four wives. The early teachings of Islam thus represented a significant step forward in terms of women's rights, and women in the early Muslim state based in Medina enjoyed legal rights on par with men. The egalitarian ethos of Muhammad's message extended beyond marriage into numerous other realms of social life. All Muslims, regardless of wealth, social standing, or tribe, were to stand equal before God, who would judge them only on their piety. Significantly, although Muhammad's message clearly established Islam as a highly communal religion, the Quran does not mandate an Islamic priesthood. Muslims are instead enjoined to read the

Quran, meditate upon its teachings, and use it as their personal spiritual guide.

Finally, the message of Muhammad sought to address Muslims' relations with non-Muslims. Christians and Jews, because they came from monotheistic traditions and believed in God and the Scripture, were to be allowed to continue to practice their faiths if they paid a tax and consented to live under Muslim rule. The Quran was much less benign concerning polytheists, who were to be fought or converted.

By the time of Muhammad's death in 632 CE, he had succeeded in forming a new community built around the teachings of Islam. The message of the Quran, the communal rites and rituals, and the different rules governing social behavior all combined to help Muhammad establish a cohesive and distinctive group based on shared identity as Muslims. Muhammad's legacy proved to be an enduring one, as after his death the *umma* would at its peak extend from western Arabia to Spain and India, and Islam would grow from a relatively small cult into one of the world's great religions.

Muhammad and the Emergence of Islam in Arabia

The life of Muhammad (ca. 570–632) is of central importance to well over a billion Muslims throughout the world today. It not only helps explain the early history of Islam but also provides a pattern of behavior replicated daily by Muslims.

Tradition holds that Muhammad b. Abd Allah was born sometime in the last decades of the sixth century in the Hijaz, a region of the Arabian Peninsula bordering the Red Sea. Prior to this period, the region possessed little strategic

QUESTIONING THE HISTORICAL MUHAMMAD

In the nineteenth century, the French historian Ernst Renan (1823–1892) proclaimed that unlike Jesus, Muhammad's rise occurred "in the full light of history." Renan implied that whereas precious little is known of the "historical" Jesus, the "historical" Muhammad is known with greater certainty. Preserved in Muslim scripture (Quran), the massive body of Prophetic tradition (hadith), and the historical chronicles (*akhbar*), an amazingly full picture of Muhammad seems to emerge. In the 1970s, however, London University scholars, such as John Wansbrough, Patricia Crone, and Michael Cook, began to question the historical validity of these sources, casting a considerable shadow across Renan's premise. Although the views of the London School were largely dismissed as too radical, a more source-critical approach to the existing historical narrative of Muhammad's life and prophetic career emerged as a consequence of this challenge.

—Rasheed Hosein

importance to either the East Roman (Byzantine) empire (330–1453) or the Sassanid (Persian) empire (226–651), the two great powers of western Afro-Eurasia at the time. The ancient trade in frankincense, which passed through southwestern Arabia, was no longer a major economic activity. However, roughly a century and a half of semicontinuous warfare between the two empires heralded great change. Due to the conflict, trade from India and China diverted from the ancient overland trade routes of the Silk Roads to one that moved across the Indian Ocean and the Red Sea. This reenergized the Arabian economy and elevated the importance of western Arabia immensely, adding great wealth to the major cities of the Hijaz.

However, the economic changes that made the Hijaz prosper created great social upheaval. Increasingly, issues of wealth and disparity and the growth of the region's cities began to tear at the traditional patterns of tribal society, as evidenced by Muhammad's early years. Tradition holds that Muhammad's father, Abd Allah (ca. 545–570), died a few months before his son's birth. Muhammad's mother Amina (d. 577) died

► THE *SIRAT RASUL ALLAH*—THE EARLIEST SOURCE ON THE LIFE OF MUHAMMAD

In terms of sources, the earliest biographical material on Muhammad comes from the historian Ibn Ishaq (ca. 704–767). Appearing roughly a century after Muhammad's death, the *Sirat Rasul Allah* (*The Biography of God's Messenger*) is one of our most valuable sources on the life of the Prophet and forms the foundation for historical inquiry. However, the original text of Ibn Ishaq is lost.

All that remains of the work are the extensive portions quarried primarily by Ibn Hisham (d. 834) in his late-eighth-century/early-ninth-century recension and quotations of the text in the work of historians such as al-Tabari (d. 923). Using the work of Ibn Hisham, al-Tabari, and 11 other historical chronicles dating from the 820s to 1449, the European historian Alfred Guillaume attempted to rebuild the original history as it was written by Ibn Ishaq. Aside from extensive portions missing from the beginning of the original *sirah* (biography), Guillaume has reconstructed the majority of the work, restoring to scholarship our earliest extant version of the life of Muhammad.

—*Rasheed Hosein*

before his seventh birthday, leaving the young boy orphaned at an early age. Although the tribal system protected his interests, it was far from comprehensive in coverage, and these traumatic events in his early life affected Muhammad's view of society and social justice. The hadith literature records that Muhammad could neither read nor write, attesting to his lack of status in the clan as an orphan. Both the Quran and the hadith later commented extensively on one's obligations to society's downtrodden, lauding the virtues of protecting widows and orphans and establishing extensive rules on inheritance.

From a fairly young age, Muhammad took part in the trading ventures of his clan, which was known as the Banu Hashim and formed an important subset of Mecca's dominant tribe of Quraysh. His acumen in business affairs brought him to the attention of Khadijah (ca. 555–619), a wealthy businesswoman in Mecca. Their partnership became prosperous and led to marriage (ca. 595). However, this new wealth only served

to deepen Muhammad's concern over Mecca's social inequalities, leading him to retreat into the nearby hills to think and meditate. According to traditional accounts, a 40-year old Muhammad (ca. 610) was in a cave on Mount Hira, located some three miles northeast of Mecca, when revelation occurred. Muslim tradition records that Gabriel, the herald archangel, commanded Muhammad to "recite in God's name" (Quran, 96:1–4), thereby inaugurating the revelations of Muslim scripture. This revelatory experience would continue, in fits, over the next 20 years of the Prophet Muhammad's life.

Generally, Quranic scholars divide the sum of Muhammad's revelations into two distinct phases: the Meccan phase (ca. 610–622) and the Medinian phase (ca. 622–630). The *surahs* (chapters) of the Meccan phase mark the earliest revelations and tend to be short and pithy. The messages contained therein are dominated by verses decrying the practices of the pagan Arabs of Mecca and describe what awaits the unbeliever in the next life. These verses were even more unnerving to the Meccan elite because their very message undercut the elites' status and power. The city of Mecca prospered in large part because it was considered a sacred enclosure (*baram*). While the system of reciprocal violence that marked pre-Islamic justice was often bloody and could last generations, this hostility between tribes could not take place inside the confines of a sacred enclosure. In this way, groups that were otherwise engaged in intractable feuds could interact and trade in relative peace. In order to reinforce the sacrosanct nature of the Meccan *baram*, the elites of the city promoted an annual fair in the nearby site of Ukaz, followed by a pilgrimage to honor the pantheon of pre-Islamic Arabian gods in the holy sanctuary of Mecca.

However, Muhammad's call for an austere and uncompromising monotheism threatened these practices, which were the economic lifeblood of the city. Despite the protection afforded him through his wealth and his clan, the Meccan elite put increasing pressure, ranging from isolation to full-scale boycotts, on Muhammad to recant his revelations. However, in the Year of Sorrows (ca. 619), both Abu Talib (head of the Banu Hashim) and Muhammad's wife Khadijah

died. In an instant, the Prophet's main sources of protection and comfort were removed from him. The subsequent leader of the Banu Hashim, Abu Lahab (d. 624), removed the clan's protection, eliminating the threat of retribution to Muhammad's enemies. In 622 Muhammad and his followers fled from Mecca and migrated northward to the oasis city of Yathrib (later renamed Medina), some 200 miles (320 kilometers) distant. This event, known as the *hijrah* (emigration), inaugurated the first Islamic polity and marks the beginning of the Islamic (lunar) calendar.

In Medina, the tenor of Muhammad's revelations changed with his adoption of political authority. The Median verses tend to be longer than the Meccan verses and focus more on regulatory and governmental issues. Due to the tenuous relationship between Mecca and Medina at this juncture, fighting between the two cities became inevitable. Thus, revelations also began to enunciate the concept of jihad (literally "striving" but carrying the meaning of "just warfare" in this context). Arguably, the most intriguing by-product of the Medina polity was the creation of the *ummah* (here meaning "community"). The various individuals adopting Islam were no longer under the protection of the tribal system, and the *ummah* provided not only a religious connection but also a social identity.

During the final decade of Muhammad's life (622–632), the nascent Muslim community in Medina struck out on some 80 raids against Mecca. The Battle of Badr (624) was the first major victory for the Muslim army. However, the stalemate of the Battle of Uhud a year later (625) almost toppled the new state. According to the established historical narrative, these raids were largely meant to challenge the trading supremacy of Mecca, although the exact nature or scope of Mecca's merchant trade in this period is unknown. By destabilizing trade, the Muslims sought to strike directly at the economic status of Mecca and, more importantly, to damage the Meccan prestige among the seminomadic tribes of the Arabian Peninsula. As the fortunes of the conflict started to favor the Muslims, tribes began to align with Muhammad against Mecca, and by 630 the Prophet was in a position to capture Mecca, which fell with only minimal resistance and bloodshed. With the fall of Mecca, the bound-

aries of Islamic power, centered in Medina, encompassed almost the entire Arabian Peninsula. However, Muhammad, now in his sixties, was frail from his exertions. In 632 the Prophet fell ill with head pain and weakness and died a few days later. In terms of his historical record, the revelations comprising the Quran form the basis for the legal, political, and social systems for much of the Islamic world, and his sayings and actions (hadith) still form a pattern of behavior for Muslims to this day. Indeed, few individuals in history can lay claim to a similar legacy.

Falsafah—Islamic Philosophy to 1000 CE

The expansion of Islam beginning in the 630s, the establishment of the Umayyad caliphate at Damascus (661–750), and the subsequent establishment of the Abbasid caliphate (ca. 750) brought the Muslims into contact with both Byzantine and Persian cultures, which included other religious, philosophical, and scientific traditions. The Islamic world was faced with assimilating a vast amount of knowledge and reconciling it, if possible, to Islam. The development of *falsafah* (a transliteration of the Greek *philosophia*) was thus significant for the history of Islam as well as the West. If not for the Muslim recovery of Aristotle and Plato, the West might not have seen the great work by St. Thomas Aquinas and others in the High and Late Middle Ages.

➤ **SELECTION FROM *ALFARABI'S PHILOSOPHY OF PLATO AND ARISTOTLE*, "ON THE ATTAINMENT OF HAPPINESS"**

"The human things through which nations and citizens of cities attain earthly happiness in this life and supreme happiness in the life beyond are of four kinds: theoretical virtues, deliberative virtues, moral virtues and practical arts. . . .

Therefore, the prince occupies his place by nature and not merely by will. Similarly, a subordinate occupies his place primarily by nature and only secondarily by virtue of the will, which perfects his natural equipments. This being the case, the theoretical virtue, the highest deliberative virtue, the highest moral virtue, and the highest practical art are realized in those equipped for them by nature: that is, in those who possess superior natures with very great potentialities. . . . It follows, then, that the idea of *Imam*, Philosopher, and Legislator is a single idea. However, the name *philosopher* signifies primarily theoretical virtue. . . . *Legislator* signifies excellence of knowledge concerning the conditions of practical intelligibles, the faculty for finding them, and the faculty for bringing them about in nations and cities. . . . The name *prince* signifies sovereignty and ability. . . . This is not possible except by great power of knowledge, great power of deliberation, and great power of [moral] virtue and art. Otherwise he is not truly able nor sovereign. . . . As to the *Imam* in the Arabic language, it signifies merely the one whose example is followed and who is well received: that is, either his perfection is well received or his purpose is well received."

The assimilation of Greek philosophy begins with the great school of translators, without whom the Greek and other works would not have been accessible to the Muslims. The assimilation of Greek knowledge began in earnest during the Abbasid caliphate, particularly under the caliphs Harun al-Rashid (786–809) and his son

Al-Mamun (813–833), the latter of whom established the Bait al-Hikmah (House of Wisdom), which housed a school of translators, a library, and an observatory. Nestorian Christians such as Hunayn ibn Ishaq (808–878), his son Ishaq ibn Hunayn, and nephew Hubaysh, among others, translated works not only from Greek and Syriac but also Pahlavi and Sanskrit into Arabic. By about 1000 CE scholars in Islamic lands (whether Muslim, pagan, Christian, or Jewish) had nearly the entire corpus of Greek philosophic and scientific works available for their studies.

Islamic philosophy, although usually characterized as Aristotelian, is rather a mixture of Neoplatonism and Aristotelianism and conflicts with Islam on issues such as the creation of the world and man, the immortality of the soul, and the resurrection of the body. Many Islamic philosophers considered it part of their task to attempt to reconcile philosophy and dogma. The first Islamic philosopher and the only Arab was Abu-Yusuf Yaqub ibn-Ishaq al-Kindi (d. ca. 870). He was called the "Philosopher of the Arabs." Al-Kindi studied and wrote on nearly all the Greek branches of science and philosophy. Although he gave due regard to philosophy, he believed in the harmony of revelation and reason and recognized the former as a higher source of knowledge. He maintained nevertheless that most of one's knowledge comes through science and mathematics. He syncretized Aristotelian concepts such as matter and form, act and potency, and active and passive intelligence with certain Neoplatonic ideas such as creation by emanation from the transcendent True One and, in doing so, inserted creation *ex nihilo* (out of nothing) into the equation. He also divided Aristotle's original two species of active and passive intellect into four, which was adopted by al-Farabi and ibn-Sina. Al-Kindi's biographer al-Nadim cataloged about 250 works of al-Kindi, only about 10 percent of which actually survive.

Al-Razi (d. 925; Latin, Razes) was the next great philosopher, skeptic, and possibly agnostic. He was known primarily as a physician and diagnostician. His philosophical system was Platonic and postulated five eternal principles: God, the soul, matter, space, and time, which clearly conflicts with the Quran. His concept of

creation postulated that the soul developed an irrational passion for matter but was unable to achieve union on its own. Thus, God created the material universe as a place in which the soul's passion could be acted out.

Al-Farabi (875–950), known as the Second Teacher (after Aristotle), was perhaps the most widely read and prominent philosopher of this early period. He was particularly well known for works on logic and was the first major theoretician of music. His classification of the sciences had an impact on Muslim thought as well. His philosophy is based on Aristotelianism but, like al-Kindi's, is mixed with Neoplatonism. At the center of his philosophy is the First Being or Absolute One, which he equated with Allah. From this absolute and prime mover, all intelligences emanated in a hierarchical order, producing the Aristotelian-Ptolemaic planetary spheres. The last emanation was the Agent Intellect, which governs the sublunar sphere and is the source of all things in that sphere, including on earth. Al-Farabi adopted al-Kindi's concept of the four types of intelligence as well and also developed a political theory heavily influenced by Plato (Aristotle's *Politics* had not been translated) in which all authority emanates from a head of state (*rais*). The *rais* controls the state, assigns men to appropriate grades in the hierarchy, and is the embodiment of the philosopher, prophet (imam, or religious leader), and king. Unlike al-Kindi, however, al-Farabi maintained the superiority of philosophy over religion. Al-Farabi is sometimes erroneously credited with developing the distinction between essence and existence. Concerning the immortality of the soul, al-Farabi held that only the souls of those who had actualized their intellect (i.e., philosophers) would survive, which was at odds with Islamic doctrine.

The development of Islamic philosophy was significant not only for the Muslims themselves but also for the development of Jewish and Christian philosophy, particularly after 1000 CE. The Muslims came into contact with Greek philosophy and science through Christian translators; just as the early Christian Church had to deal with assimilating Greek thought, so did the Muslims.

Kalam—Islamic Speculative Theology to circa 1000 CE

The expansion of Islam beginning in the 630s, the establishment of the Umayyad caliphate at Damascus (661–750 CE), and the subsequent establishment of the Abbasid caliphate in Persia (ca. 750) meant that the Muslims had to deal with various religious questions that arose from

➤ AL-ASHARI, ON THE CREATION OF ONE'S ACTS

"The rational proof of the creation of men's acts is our experience that unbelief is bad, false, vain, inconsistent, and of a certain contrariness, whereas faith is good, toilsome, and painful.

Such being the case, unbelief must have a producer who intentionally produces it as unbelief, vain and bad. And its producer can never be the unbeliever, who desires that unbelief be good, right, and true, whereas it is the contrary of that. Likewise faith must have a producer who produces it as it really is, toilsome, painful, and vexatious, and who is not the believer, who, though he strive that faith be contrary to its actual painfulness, . . . has no way to effect that. . . . [T]hen the intentional producer of both must be God Most High, Lord of the Worlds. For nobody and produce them, since bodies can effect nothing in things distinct from themselves."

Kitab al-Luma, translated by R. J. McCarthy (Beirut, 1953), 55–56, quoted in John Alden Williams, ed., *Islam* (New York: George Braziller, 1962), 191–192.

political developments, the development of religious law (Sharia), as well as coming into contact with other religious traditions, such as Christianity and Zoroastrianism. The development of *kalam* (speculative theology) is very significant for the history of Islam.

In the Umayyad period (661–750) there were discussions concerning whether the Quran was the created or eternal Word of God, and debates concerning works and faith as well as free will versus predestination. The debate concerning whether a Muslim who sins remains a Muslim and whether faith alone or works were necessary to be a Muslim was significant because of the political situation of the time, particularly the assassination of Uthman, the civil wars, and the establishment of the Umayyad caliphate in 661. The Kharijites (the Seceders, those who initially followed Ali) militantly opposed the Umayyads and believed that works not only reflected but also affected one's faith and that one did not remain a Muslim after a grave sin. The Murjites (those who postpone), who acquiesced to Umayyad rule and represented the majority of religious opinion, argued that faith alone is sufficient, that a grave sinner remains a Muslim, and that works can neither quantitatively increase nor decrease faith. The judgment of a sinner should be reserved for God alone. On the issue of degrees of faith, orthodox Sunni theology took a middle road but inclined toward the Murjite position. Arguably, the central topic of discussion, around which many of the theological schools developed, was the problem of predestination and free will. On the one extreme were the Jabirites (*jabr*: coercion, force), who maintained strict determinism; on the other extreme were the Qadarites (*qadar*: decree, power), who argued for free will and personal responsibility. Broadly speaking, those who believe in a created Quran also believed in man's free will, while those who argued for an eternal Quran also believed that God determines everything.

Kalam began to develop systematically after 750 CE during the Abbasid period, and it too was affected by politics. The first significant theological school in Islam was the Mutazilite school (those who refrain), which initiated the discussion of Islamic doctrine in terms of Greek philosophical conceptions. They attempted to

find rational proofs for Islamic beliefs. The Mutazilites held five main points: God's unity (*taubid*), which entailed allegorical interpretation of divine attributes and held that the Quran was created; emphasis on God's justice (God must reward the good and punish evil); the Promise and the Threat (i.e., reward and punishment, paradise and hell); the intermediate position (regarding a grave sinner; i.e., that he was neither a Muslim nor a non-Muslim); and "commanding the good and forbidding the evil" (i.e., interfering publicly to maintain observance of the Sharia). Regarding the issue of free will, God is bound by justice to do what is best for man (i.e., send prophets, reveal the law, etc.), but it is man's responsibility to obey, and works can affect faith.

Although the Mutazilites were politically in favor for a short time, there was both popular and intellectual opposition to their views, and when they lost political support, they were considered heretics. Indeed, the majority of Muslims, including the *ulama* (religious scholars) rejected the *mutakallimun* (speculative theologians) and their theology. Kalam was thus studied by only a very small minority in Islam. The Asharite school of theology (after al-Ashari, d. ca. 935) arose in response to Mutazilite positions. Al-Ashari (a former Mutazilite) held that God's attributes did exist and were in some way distinct from his essence. The Quran is uncreated and eternal. Therefore, Quranic phrases about God's attributes must be accepted without question. Al-Ashari rejected the Mutazilite doctrine of free will and developed his doctrine of acquisition. An omnipotent God creates both good and evil acts of man, and the acts are acquired by man. Man acts because God has given him the ability to acquire or perform the acts that God has already created. Moreover, since God is the creator of everything, he is continually creating, without which creativity all life would immediately cease. Thus, there is no cause and effect, only atomism, or occasionalism. Al-Maturidi (d. 945) developed a system almost contemporaneously with al-Ashari's. The two systems were similar, but although al-Maturidi holds that all acts are willed by God, God does not take pleasure when evil acts are performed. Although emphasizing the omnipo-

tence of God, al-Maturidi allowed for the ability of the human being to produce acts. Determinism prevailed in medieval Islamic theology, for logically only an omnipotent being can act.

The most widely discussed problem in systematic theology was the problem of being, that is, whether essence and existence are one. The theologians tended to reject any difference between existence and essence and held that essences are created at the time of their existence, while philosophers generally tended to make a distinction between existence and essence. Discussions of being among the theologians would affect discussions among the philosophers as well.

The Shia—Islam's Principal Minority, 632–1000 CE

The two major branches of Islam, Sunni and Shia, emerged on the death of the Prophet Muhammad in 632 as a result of the dispute over the leadership of the Muslim *umma* (community). The majority, who came to be known as the Sunni, proposed that the caliph (successor, or deputy, of Muhammad) be chosen by a consensus of the Companions of the Prophet (Muhammad's followers who knew him personally, in effect, almost any Muslim who lived in the time of the Prophet), while others, who became known as *Shia* (from *Shiat-ali*, party of Ali), asserted that the leadership of the Muslim *umma* should stay in Muhammad's family and should

be passed down through the generations to Muhammad's heirs. The Sunni majority supported Abu Bakr as the first caliph while the Shia insisted on Ali, Muhammad's cousin and the husband of Muhammad's daughter, Fatima. The Shia maintain that the Prophet Muhammad chose his cousin Ali as his successor but that Ali was cheated out of the Muslim leadership by a coterie of powerful Companions of the Prophet led by Abu Bakr, Umar, and Uthman, who then became successive caliphs (Commanders of the Faithful) after Muhammad died.

Abu Bakr, Umar, and Uthman each served as caliph, in succession, from 632 to 656. Abu Bakr died in 634. Disgruntled Muslims assassinated Umar in 644 and Uthman in 656. Then it was Ali's turn to be caliph. But not all the Muslims were willing to accept Ali and his reign. Aisha, who had been the Prophet Muhammad's child bride, especially objected to Ali's rule. She led an army against Ali but in the Battle of the Camel, near the Iraqi city of Basra, was defeated and sent back to Medina.

Ali had a stormy reign and after four years faced a rebellion by Muawiyah, the governor of Syria. The battle between them was inconclusive, and Ali and Muawiyah agreed that Muawiyah would succeed Ali as caliph. At this juncture, Ali was assassinated by one of his own fanatical supporters, who was outraged at what some regarded as a betrayal.

On Ali's death, Muawiyah became caliph and bought off the claims of Ali's son, Hasan, who was given a luxurious estate, wealth, and privilege for renouncing his claim to the caliphate.

Before Muawiyah died in 680, he appointed his son Yazid to be his successor. When Yazid took the throne, the garrison at Kufa, Iraq, invited Ali's second son, Husayn, to lead them in rebellion. Husayn lived in Medina, hundreds of miles across the desert. Husayn, with his family and about 72 armed followers, set out for Kufa, but before they reached the city they learned that the rebels there had come to an agreement with Yazid and had called off their rebellion.

Husayn continued his march, even though he knew he was facing certain defeat. The Shia claim that Yazid sent an army of 30,000 soldiers to intercept Husayn, but the Sunni say that it was only a small police detachment. Whatever

THE LOSS OF MUSLIM UNITY—THE SHIA VIEW

The Shia claim that when the 63-year-old Prophet Muhammad died after a short illness in 632, the body was given to Fatima and Ali to wash and prepare for the funeral. Meanwhile, Abu Bakr, Umar, and Uthman called a meeting of the Prophet's Companions to choose a successor. The Shia further maintain that the three leaders intimidated the members and forced them to swear allegiance to Abu Bakr. Then, Umar and Uthman, with a band of ruffians, surrounded Ali's house and demanded that he come out and also swear allegiance to Abu Bakr as caliph. Uthman forced his way into the house, rudely flinging the door open behind which the 18-year-old Fatima, eight months pregnant, was standing. The door hit Fatima with such force that she miscarried a son, whom the Shia especially revere. Fatima died shortly thereafter; some claim a month, others say six months later. A reign of terror ensued in which Ali's partisans were harassed and forced to give their allegiance to Abu Bakr.

Sunni deny that whole story. They claim that Abu Bakr was selected by the free choice of the Muslims and that even Ali pledged allegiance to him. Nevertheless, Ali's partisans were not reconciled and constituted a group whose festering sense of injury and loss continues to this day.

—Wilfred J. Bisson

their numbers, Yazid's forces surrounded Husayn's much smaller group and cut them off from access to the Euphrates River on the seventh day of the lunar month of Muharram. By the ninth of Muharram, Husayn's group was desperate for water. On the tenth of Muharram, Husayn's six-month-old second son, Ali Ashgar, was dying of thirst. Husayn carried the child out to the lines of the Sunni enemies and asked their commander for water for the boy. Instead of a drink, the enemy gave him death. The enemy commander shot an arrow through the infant's neck. After Husayn buried the dead child, the battle began. Husayn and his male followers were all slaughtered in the Battle of Karbala, while the women and children, including Husayn's oldest son, whom the Shia revere as Imam Ali ibn Husayn, huddled in the tents.

The Shia maintain that the Sunni victors brutalized Husayn's corpse and trampled it with

their horses. The women and children were savagely treated and loaded on camels for the trip to Yazid's dungeons in Damascus, where some, including Husayn's daughter, died of mistreatment. They were imprisoned for a year, but a groundswell of popular support persuaded Yazid to release and return his victims to their home in Medina.

Husayn's martyrdom at the hands of the Sunni majority has become the focal point in the Shia religious outlook. The Shia built a shrine to memorialize the site of the battle, and the holy city of Karbala grew up around the shrine. The commemoration of Ashura, the day of Husayn's death, is the holiest of days on the Shia holy calendar. For the Shia, the agony of Husayn's martyrdom is the emotional equivalent of the passion of Christ for Christians, and very much like some Christian penitents during Holy Week, many Shia scourge themselves and perform other acts of self-inflicted pain to share the suffering of their Imam.

After the death of Husayn, the Shia recognized his son, Ali ibn Husayn as Imam, or holy leader. (For the Sunni, an imam is simply a prayer leader, but when the Shia speak of the Imam [capitalized], they mean Ali or one of his descendants.) The Shia believe that their Imams were appointed by God and could communicate with God. Like the pope, Shia Imams were (and are) believed to be infallible in matters of faith and morals. Shia count Ali as the first Imam, Hasan as the second, Husayn as the third, and Ali ibn Husayn as the fourth. The great majority of Shia, the Twelvers, believe that the position of Imam passed down through 12 generations of Muhammad's descendants, but Ismailis, or Seveners, hold that the line of Imams ended with Ismail, the Seventh Imam. All of these Imams except the last, according to Twelver Shia doctrine, died either of poison or were beheaded by Sunni authorities. The Eleventh Imam died in 874, when the son, Mohammed al Mahdi, who became Twelfth Imam, was only five years old. To protect him from Sunni persecution, the boy was hidden from the public.

Although Sunnis deny that there ever was a Twelfth Imam, the Twelver Shia claim that he remained hidden and miraculously disappeared in 939. The Shia faithful say that the Twelfth Imam

is hidden or, as they say, is in occultation, where he will stay until God calls him out to lead the world as the Mahdi, or messiah. Thus, Twelver Shia believe that there will be a second coming of the Twelfth Imam, even as most Christians believe in the second coming of Christ.

Shia doctrine held that the Prophet Muhammad had imparted to his son-in-law, Ali, a special message or knowledge, hidden from the mass of the faithful; that this esoteric knowledge, which guaranteed the Imams' infallibility in faith and morals, passed down the line of successive Imams to the twelfth (or the seventh, for the Seveners); and that after the occultation of the Twelfth Imam, a succession of four *wakils* (representatives or interpreters) spoke for the occulted Twelfth Imam until the last wakil died in 940 CE after refusing to name a successor. Since then, Twelvers have chosen a group of learned and pious clerics, known as *ayatollah* ("signs of God"), who can be privy to some sacred esoteric knowledge and exercise some of the Imams' infallibility.

Throughout this era, Shia Islam was a movement of dissent and revolution. In the Umayyad and Abbasid caliphates (except for a brief period at the beginning of Abbasid rule and during the dominance of the Shia Buyids in Iraq and Iran after 945 CE), the Shia were suppressed, sometimes savagely, by Muslim governments. The Shia were an underground protest movement. For the Shia, particularly the Twelvers, their victimization was one of the main themes of cosmic history.

The Sevenser Shia, or Ismailis, were, in the tenth century and later, politically more successful than the Twelvers. An Ismaili group, which claimed their leader to be a descendant of the Prophet, seized power in western North Africa in 909. They conquered Egypt and part of Syria in the late tenth century and established the Ismaili Fatimid caliphate that endured until 1171. The Ismailis developed an elaborate theology that, like the philosophy of the sixth-century BCE Pythagoreans, focused on the mystical power of numbers, particularly the number seven, and the role of esoteric knowledge. The Ismailis taught that there are levels of knowledge, which only the elite theological adepts can know; that (for example) within the ordinarily understood "outer" mean-

ing of the Quran there was an inner meaning that Muhammad had imparted to Ali and that could be accessed by a few pious Ismaili adepts.

The Development of Sunni Orthodoxy, 632–1000 CE

The idea of a Sunni orthodoxy in the early centuries of Islam is a complicated and somewhat problematic issue for historians. While one may use the term "Shia" (short for *shiat Ali* or "party/faction of Ali") for the political supporters of Ali b. Abu Talib (r. 656–661) after his death, the same sort of crystallizing moment is missing in Sunni Islam. Most Western scholars view the full development and articulation of Sunni theology and law as a long process that culminates in the ninth century or later. However, there are definite events and historical figures from this period that scholars point to as forming the core of Sunni Islam, which not only binds more than three-quarters of the world's Muslims into an identifiable group but also links them with Islam's more than 14 centuries of history. In this way, many scholars choose to use the term "majority Islam" to describe the Sunni Islam of this age, wherein acceptance of the legitimacy of the first three caliphs (successors) after Muhammad and adherence to one of the developing legal schools were some of the primary methods of distinction between Muslim groups.

The term "Sunni" refers to the Arabic word *sunnah* (customary practice) and is derived from the Arabic formula *abl al-Sunnah wa al-Jamah* (the People of the [Prophet's] Customary Practice and Community). In the first Islamic century, the concept of *sunnah* was used to address the legal and ritual issues that faced the

► CHARITY AND PIOUS ENDOWMENTS IN EARLY SUNNI PRACTICE

With the death of Muhammad in 632, Muslim intellectuals began to develop and refine their understanding of the ritually binding aspects of the religion (known in Arabic as *ibadat*). One of these pillars of the faith is the concept of charity. According to the Quran (9:103–104), it was possible to donate portions of an individual's wealth (in either coin or kind) as an act of repentance. However, while the hadith (prophetic sayings and actions of Muhammad) records the first instances of official charity in the Prophet's lifetime, it was not until much later that the legal rules surrounding charity were fully articulated.

Almsgiving, known in Arabic as *zakat* (from the Arabic verb for “to increase” or “to be pure”), is the most visible form of charity in Islam. According to the hadith and the interpretation of legal scholars, the rate of *zakat* that a Muslim must pay was roughly 2.5 percent of one's valuables and savings held for an entire lunar year if their wealth exceeded the value of (roughly) three ounces of gold.

There was a separate formula for livestock, agricultural goods, and coins. Likewise, there were rigid rules to limit those who could receive *zakat*.

However, the giving of alms was not the only charitable venture open to believers. The practice of endowing something for religious purposes, known in Arabic as a *waqf* (pl. *awqaf*) became quite popular in the Islamic world. An individual would declare a piece of property (or build something, such as a school) to be used for religious purposes. This served two purposes. It created institutions that promoted Islam (such as religious schools, mosques, and soup kitchens), and the property became ineligible for taxation by the state. Additionally, the creator of a *waqf* could name the terms of the endowment, often naming heirs in perpetuity as the paid administrators. In this way the *waqf* came to be a way to keep land from the state fisc and prevent a government from confiscating rich or lucrative properties.

—Rasheed Hosein

community. It was used to cite precedent, arguing that the customary practices of the Prophet Muhammad (ca. 570–632), his earliest companions, and in some cases those of the pre-Islamic Arabs and prophetic figures were legally and ritually valid patterns of action and conduct in the new Islamic milieu. In this way the Sunnis saw (and continue to see) themselves as a single coherent and unbroken community based upon the continuation of the practices ascribed to the Prophet Muhammad, his earliest followers, and those pre-Islamic customs that did not contradict the Quran.

However, while this was the majority view, it was not the only model. Existing within the early community were two basic political-religious positions. In the case of the Shia, they were initially motivated by the charisma of Ali and his descendants. The Sunnis, though, accepted the caliphal institutions that evolved after the death of the Prophet. These basic views in the early Islamic period were further defined by W. Montgomery Watt as intrinsicalist and contractualist and approached the issue of *sunnah* legitimacy in different ways. The intrinsicalist view held that legitimacy (both political

and religious) was a function of personal charisma, which was intrinsic or inherent to certain individuals—such as the aforementioned Caliph Ali—and very reminiscent of the ancient Near Eastern notions of sacral kingship. The intrinsicalist also viewed those imbued with the political-religious charisma as living exemplars and interpreters of the *sunnah*. In comparison, the contractualist view held that this charisma, which was intrinsic to Muhammad, was routinized or incorporated within the institutions of power and spirituality that were developing in the early caliphate. In this way, authority became something that was conferred and was transferred through the giving of an oath of allegiance (*biyah*). The *sunnah* became the practice of not only the Prophet but also those of his whole community, tying individuals concretely into the aforementioned Arabic formula: *abl al-Sunnah wa al-Jamah*. Thus, the wider view of political and spiritual legitimation inherent to the contractualist position resonated with the majority of the community and formed the dominant outlook in early Islamic society.

However, within the contractualist conception of Islam, the appurtenances of Sunni Islam

came into being only after the contentious theological debates of the second and third Islamic centuries (roughly the eighth and ninth centuries CE). The *ummah* (community of believers) of this period began to seek answers to weighty questions of a spiritual and theological nature, and since the *sahabah* (Companions of the Prophet) were now gone, the community began to experiment for solutions. Due to the new economic and intellectual wealth and power that was gained after the conquest period, Muslim theologians came into contact with Greek and Persian philosophy, leading to an expansion of Islamic philosophy. The outgrowth of this was a movement popularly referred to as the Mutazilah (those who separate themselves) but rightly by the more formal title, *ahl al-Adl wa al-Tawhid* (the people espousing [divine] justice and unity). Under the caliph al-Mamun (r. 813–833) these debates became violent, as the Mutazilites received official support for their philosophic views. However, the speculative theology of the Mutazilites would soon fall out of favor, as its abstractions were ill-suited to meet the majority's growing needs for broader clarifications of religious and legal practice.

A major part of this broader clarification revolved around the sources that would become the core of Sunni orthodoxy. There are considered to be four sources of legitimacy in majority Islam: the Quran, which is the primary source of religious, social, and political thought; the hadith (literally speech, but in this context meaning prophetic tradition and including the Prophet's speech and actions); *ijma* (consensus), wherein the community reaches agreement on the legal issues using both the Quran and the hadith; and finally *qiyas* (analogous reasoning), where one patterned solutions on other judgments when there was not a direct answer in either the Quran and hadith. These last two sources of authority harkened back to the original idea of community in the majority Sunni formula, a notion that developed around the prophetic hadith that stated: "My people will not agree together on an error."

While the Quran was the unquestioned central and primary source for Islam, it sometimes lacked specific details for everyday life. Unlike the Shia and their belief in the charismatic authority of an imam (a divinely chosen leader in this context) who served as a living model for

these issues, the Sunnis had to ground their orthodoxy in the established *sunnah*, leading to the question of what constituted authentic traditions and customary practices at this early juncture. After the death of the Prophet, people began to relate his deeds and sayings orally, unintentionally preserving them. However, it was not until the third Islamic century that this oral tradition, known as hadith, was systematically recorded by the great Sunni collectors.

Of the major collections of hadith, two are particularly important to Sunni jurists and theologians. The first is the collection of Muhammad b. Ismail al-Bukhari (810–870), or Bukhari for short. His work, known under the title *al-Jami al-Sahih* (*The Authentic Collection*), is considered to be the most trustworthy of the hadith compilations. The other major work in this genre belongs to Bukhari's student Abu al-Husayn Muslim b. al-Hajjaj (821–875) and is known simply as *Sahih Muslim* (*Muslim's Authentic [Traditions]*). Together these two works set the standard for relating the traditional sayings and deeds of the Prophet.

One important feature of the hadith genre was the *isnad* (chain of authority). In each extant entry the compiler recorded the chain of authority of the prophetic tradition back to the original witness or in some cases to Muhammad himself, thereby presenting a proof of its authenticity. However, even at the time that these hadiths were being compiled, there were serious questions arising about the veracity of some of them, leading some Western scholars to question the validity of the entire genre. Thus, while treated with skepticism from some Western scholars, from a Sunni point of view these works are beyond reproach and are considered a critical bridge to answering issues that are not addressed directly in the Quran.

In order to use the Quran and assess the hadith, the Muslim community began to work out a law code to help with the questions of orthopraxy (correct behavior). The answer came in the form of the Sharia (literally meaning the "way to the water hole" or "straight path" but now carrying the meaning of "Holy Law"). This divine law, culled from the Quran and hadith, contained everything that the majority community needed. In the pre-Islamic period a rough system of law was in place wherein justice was

dominated by the notion of sanctioned vengeance and collective culpability. For example, if one party wronged another, then the wronged side could legitimately demand or inflict a corresponding punishment on one or more relatives of the perpetrator to even accounts. Under Muhammad, the rules of such conduct were spelled out so that the principle of *thar* (blood revenge) changed to *qisas* (just retaliation). It is important to note that this change only abrogated the pre-Islamic notion of collective culpability, limiting liability to the perpetrator of the crime; it did not alter the right of the wronged to demand a reciprocal punishment.

However, while both the Quran and the hadith were largely static by the end of the ninth century, communal consensus (*ijma*) and analogous reasoning (*qiyas*) were not, and as legal issues became more complicated the notion of *fiqh* (jurisprudence) developed. The term *fiqh* came to apply to any legal decision that required the independent (i.e., not directly addressed in the Quran and hadith) exercise of human intelligence and was the opposite of *ilm* (here understood as divine knowledge). This led to differing views on legal questions, which spawned the articulation of differing Sunni legal positions. Emerging from the serious political and religious debates of the period were the four Sunni legal schools (s. *madhbab*, pl. *madhdbabib*) that survive to this day: the Hanafi *madhbab* (ca. 767), the Maliki *madhbab* (ca. 795), the Shafi *madhbab* (ca. 819), and the Hanbali *madhbab* (ca. 855). In this way, the majority community formed a collective enterprise, supervised by the theologians and the jurists. It is important to note that each of the four schools considers the others to be fully orthodox, and while their origins and histories were varied, they mark the final articulation of Sunni development in the Cassical Period.

Religious Pluralism and Toleration in Muslim Spain, 711–1100 CE

In 711, the Christian Visigothic kingdom in the Iberian Peninsula was invaded by the Muslim Berbers of Northwest Africa. This invasion was conducted under the auspices of the Umayyad caliph, Al-Walid I of Damascus, and within two years his army was well under way toward conquering the area. By 719, the only areas that were not under the authority of the Umayyads were the Kingdom of Asturias, which is modern-day Galicia, and the Basque regions of the Pyrenees. The rest, known to the Romans as Hispania and Lusitania, were now named Al-Andalus by the Umayyads.

Although the new Muslim regime was a devout one, religious intolerance was not universally applied, for those polytheists and idol worshippers still existing among the Visigoths were given the choice of “Islam or the sword.” However, those who were considered “people of the book,” namely Jews and Christians, were allowed to become protected people, or *dhimmis*. They were given the rights to practice their religions freely and maintain their places of worship, provided that they pay the *jizya*, or nonbeliever tax or tribute, that was levied upon adult males who were of a certain economic level. These communities were also given a certain amount of autonomy and were allowed to keep their previous government, the head of which was responsible for sending over the tax or tribute. As a result, most non-Muslims were not encouraged to convert to Islam, and some were even encouraged to remain with their

faith, as the *jizya* provided a substantial amount of revenue for the caliphate.

In addition to being allowed to practice their own religion, the Christians were allowed to send their children to either the Muslim schools or, if they objected to this, to schools attached to their own churches. Christian schools thrived as early as the ninth century, although these schools mainly produced theologians. There is historical debate over the extent of Muslim religious tolerance; however, many churches and monasteries remained in existence after the fall of the Visigoths, and there are no recorded incidences of iconoclasm. The main interference posed by the Muslims was in the appointment of church officials. They reserved the right to appoint or remove all church clerics, a power that was used from time to time. Sometimes the kings used this power as a method of earning revenue by selling offices to the highest bidder. At times, the positions of absentee bishops were even awarded to Muslims and Jews. As for the Jews, they enjoyed the same rights to religion as the Christians. The synagogue at Toledo remained active, and several translating centers were opened using Jewish translators. Under the Umayyads, the Jews enjoyed more toleration and religious freedom than they had under the Visigoths. They opened Talmudic schools, and poetry written in Hebrew flourished during this period.

Many of the Christians living in Al-Andalus began emulating the characteristics of Arab society and many converted to Islam. These people, known as Mozarabs, adopted the customs, dress, names, and even Arabic language. Those who converted to Islam were saved from paying the *jizya*. However, even though these *musalims* (the name for the converts) were now technically Muslim, this still did not afford them or their children (*muwalladun*) political or social equality with the Arab Muslims. This caused some to convert back to Christianity later on, and this same population sparked rebellions in the eighth century due to social inequalities.

By the end of the eleventh century, the Muslim princes were gradually losing their power in the Iberian Peninsula. Christians had been pushing their way south from Asturias through modern-day Portugal. The Almoravids were called from North Africa to assist, and this re-

sulted in the takeover by the Almoravids in 1096 and the reunification of Muslim hegemony, albeit in a smaller area of the Iberian Peninsula because the Christians had made some headway. The Almoravids were stricter about their religion than the Umayyads had been, resulting in harsher conditions for non-Muslims. Although Christians and Jews were still allowed to practice their religions, they received social restrictions that they had never experienced before. Both groups were forced to live either in special sections of the cities or were forced to move outside of the cities altogether. Jews were also given special garments to wear so they could be easily identifiable. These tactics angered the non-Muslims and drove them to assist in the more vigorous attempts of the Christians to drive out the Muslims.

Islamic Law—Sharia

Islam teaches that the basic human problem is ignorance; consequently, humans need guidance to achieve salvation. Following Islamic law or Sharia leads one to be rightly guided on the path to salvation. Sharia developed from the need for specific guidance on personal questions. Specific guidance to questions was given as a fatwa by religious scholars and judges.

Islamic law was developed from the Quran and from the hadiths. The Quran (scripture) is believed by Muslims to have been given as revelation to Muhammad by an angel from Allah. The hadiths (traditions of sayings and deeds) were recorded after Muhammad's death. They contain reports of his behaviors and sayings (*sunnab*). Muslims believe that Muhammad lived and spoke things that can be used for guidance. In effect, the hadiths are coequal with the Quran. The combination of the hadiths of Muhammad and the Quran are the basis for Sharia.

► SHARIA AND ENGLISH COMMON LAW

Sharia law and English common law were both produced during the Middle Ages and were the products of reasoning by individual judges in individual cases in a process that is called casuistry. Both developed to serve the needs of a developing community: religious in the case of Sharia, civil in the case of common law. Neither system emerged from statute or a law code but instead both evolved more or less on a case-by-case basis. In that sense, both are organic bodies of law, closely reflecting their political and social contexts. In neither society was there a separation of religion and state. Both spread to new lands far beyond their origins.

Sharia came first, developing after the death of Muhammad (632 CE) and the great successes of his followers. New situations arose in which legal decisions were necessary, making the decisions unprecedented. Ancient customs of the desert did not provide adequate legal principles for making a decision. Sharia supplied the need.

Sharia developed from Islamic judges making decisions in the areas of life that were encouraged, permitted, neutral, discouraged, and prohibited. The decisions were intended to provide Muslims with guidance in matters of conscience. The judges were not part of an organized legal system but instead were part of an informal system. Their opinions were binding upon their consciences. The key legal principles for reasoning about the facts of a case were found in the Quran, the hadiths, elements of Roman law adopted from the Byzantines, and other ancient traditions.

Theoretically, Sharia covered all types of cases that could arise in an Islamic society, but in common practice the caliphs, sultans, sheiks, and others kept some legal matters, especially those involving political offenses or money, under their control.

Over a roughly 300-year period (700–1000 CE) the schools of Islamic law that arose developed a body of binding opinions. By around 1000 Sharia was fairly fixed.

In contrast, English Common Law began after the Norman Conquest (1066 CE). Over a 200-year period the kings of England sent itinerant judges on judicial circuits around the realm. Using reason, the older Anglo-Saxon unwritten customary law, and some other sources, they developed the law common to all of England and the establishment of precedents.

The English judges became legal specialists in three types of royal courts, turning written opinions in individual cases into a growing body of law between 1100 and 1300. These courts were the Court of Common Pleas, the Court of King's Bench, and the Exchequer of Pleas. By 1300 the legal principles of the Common Law were increasingly fixed as they were in Sharia. However, to prevent injustices arising from the rigidity of the Common Law, decisions mandated a fourth type of court (Chancery) to provide justice (equity).

An important commonality between Sharia and Common Law was in the influence of religion. Sharia was believed to be the interpretation of divine will. Common Law judges were also appealing to the divine by finding the universal moral principles of all peoples.

—Jack Waskey

Hallaq, Wale B. *The Origins and Evolution of Islamic Law*. Cambridge, UK: Cambridge University Press, 2005.

Hudson, John. *The Formation of the English Common Law: Law and Society in England from the Norman Conquest to Magna Carta*. New York: Longman, 1999.

The content of Sharia includes the divine decrees of Allah. The decrees are binding upon everyone. These rules include duties owed to Allah (*ibadat*). The word *ibadat* comes from the word for slave (*abd*), and thus the Muslim believer is the slave (*abd*) of Allah in that his word is the believer's command. In contrast, duties that are owed to people are called *muamalat*.

No human actions are to be found outside of Sharia. It places all of human behavior inside of five categories. These are things that are obligatory (*fard*), things that are recommended (*mandub*), things that are permitted (*mubah*), things that are discouraged but not prohibited (*makruh*), and things that are absolutely forbidden (*haram*).

Muslims believe that the Quran is the revealed will of Allah; however, to apply the revelation to human actions requires the practice of *fiqh*, which is the science of jurisprudence. The rules for governing life are derived from the issues of life and the data of the Sharia. Another tool used to develop Islamic law is analogical reasoning (*qiyas*). It was to be used when the other rules could not provide an answer to a question.

The rapid pace of the Arab Muslim conquests pressed its rulers to create a system of order that was comprehensive enough to control all of society. At first the Muslim Arabs had only their traditional ethical codes. However, as people in the conquered parts of the Byzantine empire converted to Islam, they brought some of the elements and practices of Roman law to the development of Islamic law. One figure that was adopted was the Roman magistrate, who became a *qadi*, or judge, who applied the law.

The goal was to create a society so ordered that morality, social relations, economics, and politics were all governed by the religious law of Sharia so that every aspect of the lives of individuals, of business life, and of sociopolitical life were regulated by it. Also regulated are the religious and ritual rules that govern fasting during Ramadan, foods that can be eaten, contracts, worship, payment of alms, sumptuary rules, and even the attitudes that are permissible when choosing a spouse.

Many schools of Sharia emerged during the early history of Islam. Eventually four schools (*madhabib*) acquired large followings among Sunni Muslims. Each Sunni school took its name from its leading legal scholar. The schools that became the main schools that set the standards were the Maliki, Hanafi, Al Shafii, and the Hanbali.

The Maliki school was founded by Malik ibn Anas (ca. 715–796). A conservative-minded individual, he worked in Medina. His jurisprudence was widely received in North and West Africa.

The Hanafi school was named after the legal scholar Abu-Hanifa an-Numan (699–767). It became the school with the greatest number of adherents in India, Pakistan, Bangladesh, Turkey, and Afghanistan.

The Al-Shafii school was founded by Abdullah Mohamed Ibn Idris Al Shafii (767–820). It arose in Egypt and expanded into Syria, Indone-

sia, and East Africa. Al Shafii created a widely accepted jurisprudence. He argued that there were four sources of law (*usul al-fiqh*) that stand in a definite order of rank. The first is the Quran with its commandments of Allah. The second is the *sunnah* of the prophet if transmitted by a valid hadith. The third is the legal scholar (*faqih*) who may look for consensus (*ijma*) of the community in the past. The use of consensus (*ijma*) is derived from a saying of Muhammad's that declared that the Islamic community shall never agree on an error. This means that the consensus of the learned and pious of previous generations and the contemporary community can be trusted as a sure guide.

The strictest of the four schools was the Hanbali school, founded by Ahmad ibn Hanbal (780–855). It rejected innovation and adopted traditionalism.

Shia Islam developed its own schools of Islamic law. The two major Shia schools were the Ja'fari and the Zaydi. The Ja'fari school takes its name from Ja'far al-Sadiq (702–765), the sixth imam of the Twelver Shia. The Shia Zaydi (Zaydiyyah) school developed among the Zaydis of Yemen. They are followers of Zayd ibn Ali, the grandson of al-Husayn ibn Ali.

Other schools of ancient Islamic law were the al-Ibadiyyah (Ibadi), Thahiri, Sufian Al'thawree, Sufian bin O'yayna, and Layth bin Sa'ad schools. The al-Ibadiyyan school was founded in Oman about 50 years after Muhammad's death. Neither Sunni nor Shia, it took its name from 'Abdullah ibn-Ibad at-Tamimi (fl.685), a Kharijite.

The Thahiri school of jurisprudence was developed in Andalusia by Ali ibn Hazm (fl.1015). He advocated relying exclusively on the literal meanings of the Quran and the Sunna.

The great bulk of Sharia was formulated in the Middle Ages. It was closed to changes by the 1200s.

The Mutazilites and the Evolution of Sunni Orthodoxy

The Mutazili were an influential Muslim theological tendency and quasi-political faction that flourished principally in Baghdad from the eighth to the eleventh centuries CE. Mutazilism seemed to be on the verge of becoming the orthodox position of the Abbasid caliphs but ultimately fell out of favor and was suppressed as a heresy.

The Mutazila represent the early philosophers and theologians in the development of Islamic thought. Whereas schools (*madhhabs*) within Islam are most often associated with jurisprudence (*fiqh*), the Mutazili focused almost exclusively on the more speculative topics of philosophy and theology. They adopted a rationalist approach to their philosophical method that incorporated logical reasoning, materialism, and elements of Hellenistic philosophy. This represents a turn in the development of Islamic theology. Whereas earlier focus had concentrated on the different positions within Islam, the Mutazila engaged Muslim and non-Muslim approaches and subsequently developed an early apologetic tradition within Islam. Though the school itself did not continue much beyond the ninth century, its influence carried on in other traditions, such as the Ibadis and Twelver Shia. Mutazili influence was not confined to Islam. One can also find Mutazili elements within the Jewish philosophy of that period. It was a short-lived school that has had a lasting influence.

The theological school of the Mutazila arose in the early eighth century in Basra. Mutazili theology was strictly rationalist. All fundamentals of religion, such as the existence of God, his attributes, and the nature of good and evil, were to be known by reason rather than revelation, and revealed texts must be judged and interpreted by reason.

Mutazili doctrine was developed on the basis of five principles:

1. *Tawhid*, uniqueness of God. This involved rejection of anthropomorphism and corpo-

reality of God and denial that his attributes are additional to his essence.

2. *Adl*, justice. God is just; he does not create or will evil, although he is all-powerful. He gives humans freedom to act and does not impose on them what is beyond their capability.
3. *Al-Waad wa l-waid*, promise and threat. God will reward the obedient in the hereafter and punish the disobedient unless they repent before death.
4. *Al-Manzila bayn al-manzilatayn*, the intermediate position of the unrepentant grave offender.
5. *Al-Amr bi l-maruf wa l-nahy an al-munkar*, the obligation to order what is good and prohibit what is reprehensible.

Concerning the imamate (caliphate), the Mutazila held that caliphs lost their legitimacy by acts of injustice and oppression. The Mutazila upheld the legitimacy of the first four caliphs but repudiated the legitimacy of Muawiya and most later caliphs.

Under the early Abbasid caliphate, the school could propagate its teaching relatively freely and spread to most regions of the Muslim world. Its systematic theological thought was developed in debates with Sunni, Shia, and Kharijite schools and in refuting non-Muslim, especially dualist and trinitarian Christian, religious thought. In the late eighth century two prominent theologians, Abu l-Hudhayl al-Allaf (d. 840) and Ibrahim al-Nazzam (d. 845), were competing for the leadership of the school, and their distinctive views significantly influenced its further development. The inquisition (*mihna*), which the caliph al-Mamun (813–833) instituted against the opponents of the doctrine of the created nature of the Quran, is often erroneously described as the Mutazili inquisition. Al-Mamun in fact upheld divine determinism against the key Mutazili doctrine of justice and human free will and was advised by non-Mutazili theologians. The Mutazila, however, asserted the created nature of the Quran as did other theologians. When the caliph al-Mutawakkil (847–862) reacted against the inquisition and backed traditionalist Islam, the Mutazila became subject to government persecution.

In the later ninth century, the teaching traditions of the Mutazila were further elaborated and expanded beyond the confines of theology, especially by the development of an intricate conceptual framework, theories of natural science, and legal methodology (*usul al-fiqh*). Two major branch schools, the Basran and the Baghdad, now became established. The Basran school doctrine was basically defined by Abu Ali al-Jubbai (d. 915) and by his son Abu Hashim al-Jubbai (d. 933), who critically modified some of his father's teaching. The Baghdad school was headed by Abu l-Qasim al-Balkhi al-Kaabi. In Sunni Islam, Mutazili theology became mostly associated with the Hanafi legal school. Among the Shia, it was now broadly adopted by the Zaydiyya and to some extent by the Imamiyya (Twelvers). At the same time, two major antagonistic theological schools, the Ashariyya and the Maturidiyya, arose and upheld Sunni traditionalist dogma against Mutazili rationalist theology. The Ashari school was founded by Abu l-Hasan al-Ashari (d. 936), a pupil of Abu Ali al-Jubbai, who adopted a Hanbali creed. The Maturidi school was founded by Abu Mansur al-Maturidi (d. 945) in Transoxiana, who criticized Mutazili teaching on the basis of the Hanafi fiqh, a school of Islamic jurisprudence.

Mutazili theology spread at this time also outside Islam, especially among Jews, both Rabbanites and Karaites. Fragments of works by Mutazili authors of this age have been preserved in the storerooms of synagogues in Cairo. In 1027, a few years after the death of Abd al-Jabbar, Rayy was sacked, however, by Mahmud of Ghazna, who burned the libraries of the Mutazila and prohibited their teaching in the name of Sunni orthodoxy. The school never quite recovered from this blow, as successive governments sought to suppress it. Only in Khuwarizm in central Asia was Mutazili theology still openly taught, and it prevailed among Hanafi scholars for some centuries.

The school of Abu l-Husayn al-Basri was invigorated a century later in Khuwarizm by Rukn al-Din Mahmud ibn al-Malahimi. Ibn al-Malahimi (d. 1141) originally belonged to the Bahshamiyya but adopted the teaching of Abu l-Husayn and elaborated it systematically in his books. He undertook in particular to counter the philosophi-

➤ ABU L-HUDHAYL AL-ALLAF— MUTAZILITE STALWART

Abu l-Hudhayl al-Allaf (ca. 751–840) was a primary force in the shaping of Mutazila thinking in particular and Islamic theology in general. His legacy is remarkable, especially since none of his writings survived. His ideas are known only through the way he influenced the thought of others. Abu l-Hudhayl was an apologist for Islam, and he forged his thinking in the refutation of other philosophical and religious approaches. However, in the process of doing so, he maintained openness in adopting some of the methods of his opponents. In particular, he drew upon Aristotelian philosophy and placed an emphasis on atomistic metaphysics. His stress on these topics would define theological and cosmological debate within Islam for generations to come. His openness to these ideas was predicated on his emphasis on reason as a way to apprehend truth. He taught that the source of truth was not confined revelation alone, which may lead one to disassociate Islamic theology with the ideology of others. Instead, by championing the use of reason, he expanded the points of contact among Islam, Greek philosophy, and other religions. In the end, he is remembered as a staunch advocate of Islam while introducing Islam to the philosophical approaches of others. This earned him the distinction of being one of the first speculative theologians whose approach would expand the scope of Islamic thought.

—Abdulrahman Al Salimi

cal theology and metaphysics of the philosopher Avicenna (980–1037) and his school and wrote a major refutation of their theories. Al-Basri's work became influential among the Zaydi and Imamiyya (Twelvers) Shia but remained largely unknown in Sunni Islam.

A Historical Controversy— To What Extent Did Religious Pluralism and Toleration Prevail in Muslim Spain before 1000 CE?

At the time of the Islamic invasion in the early eighth century, the majority of the population of the Iberian Peninsula had been Roman Catholic; there were also significant Jewish communities in the region, perhaps dating back as early as the Roman empire. Muslim attitudes toward Christians and Jews in the conquered western Mediterranean territories under Andalusī Umayyad rule (756–1031 CE) had largely been one of tolerance, defined as consideration for the beliefs of what were called the People of the Book (*ahl al-kitāb* in Arabic), referring to the other Abrahamic faiths with a sacred or revealed text. Christians and Jews were held accountable to their own religious courts and often lived in their own areas of the city; however, they were required to pay higher taxes and oftentimes had social or other financial restrictions placed on them with varying levels of compliance and/or enforcement. Nevertheless, geographical proximity and prolonged economic and cultural contacts among the three faiths in Al-Andalus (the Arabic name for Islamic Spain) in this period has often been described by the Spanish term *convivencia*, a word first used by the renowned Spanish historian Ramón Menéndez Pidal and later expanded upon by his student, Américo Castro. *Convivencia* can be loosely translated as “coexistence,” but some historians have questioned the rather rosy picture of cross-confessional relations that Castro depicted in his writings.

One recent effort considering this controversy can be found in the writings of a specialist in Islamic Spain, María Rosa Menocal, in her work titled *The Ornament of the World: How Muslims, Jews, and Christians Created a Culture of Tolerance in Medieval Spain* (2002). Menocal's thesis stresses the positive interaction of the different religious groups in the region, and her goal is to reclaim the history and literature of Al-Andalus rather than to dismiss its importance, as medieval European historians typically do, or to view the period nostalgically, as Arab and Muslim historians have often done. Her work is in part a series of vignettes that cover the entire period of Islamic rule in the region (711–1492 CE) as well as a concluding chapter considering the Moriscos, Muslims living under Christian rule who were ultimately expelled from Spain in the early seventeenth century. These literary and historical accounts, when applied to the broader context of the history and culture of Al-Andalus, not only demonstrate the largely peaceful coexistence and exchange under most periods of Muslim rule that typified relations among the different confessional groups in Islamic Spain but also is a reflection of the powerful long-term influences of this region on the history and culture of what will become the Renaissance in western Europe and thus an important foundation of the modern Western world.

In contrast to Menocal, Bernard Lewis, who has published numerous books on Islam and relations with Christians and Jews and the West, subscribes to a more conflictive and confrontational approach in his writings. Rather than considering coexistence or *convivencia*, Lewis emphasizes a theory based on the clash of cultures whereby these religious traditions were more often in conflict and competition than cooperation. His writings are not specific to Islamic Spain but instead cover the whole gamut of what has traditionally been considered the Islamic and/or Western worlds. He writes in broad general terms and often takes his studies up to the present day. In his book *Islam and the West* (1993) Lewis presents his own definitions of terms and suggests in the last chapter that coexistence (he does not use the term “*convivencia*”)

denotes equality and that tolerance indicates that the ruling group allows the minority to benefit from and appreciate the same privileges and rights as the dominant group, a kind of separate but equal philosophy rather than one of emphasis on cultural cooperation and exchange, as Menocal stresses.

By the time of the last Islamic dynasty of Al-Andalus, the Nasrid Kingdom of Granada (1237–1492), 300 years of Christian expansion southward, and the frequent warfare along the borders had rendered *convivencia* a thing of the past. However, in the earlier centuries of Islamic Spain under the Andalusi Umayyad caliphate, tolerance, defined as consideration of and allowance for (but not necessarily acceptance of) different religious traditions, was the norm under the Andalusi caliphate. There were occasional exceptions, of course, but the overall concept of

coexistence is one of the enduring legacies of Islamic Spain.

■ Introduction: Early Medieval Monasticism

Monasteries are religious institutions in which religious devotees live an ascetic life, renouncing wealth and married life and promising obedience to the rules of the monastery. Many early medieval religions had (separate) monasteries for both men and women. The most numerous and historically important monasteries were among Buddhists and Christians, but Daoists, Manicheans, Hindus, and others supported varieties of monastic institutions.

The earliest Buddhist monasteries arose in the late centuries BCE as retreats for wandering Buddhist monks to take refuge during the rainy season. By the early medieval age, Buddhist monasteries had developed into year-round all-season institutions devoted to education and religious practices. A few monasteries became virtual cities, with thousands of monks. Buddhist monasteries were often supported by donations from the pious laity, often wealthy merchants who sought, by their donations, to win religious merit. Kings, emperors, and other

rulers often founded monasteries and endowed them with land and enserfed peasants to supply an income to support the monks.

Wealthy merchants and local rulers along the Silk Roads established many monasteries. These monasteries functioned not only as institutions to dispense religious solace but also at times hostels for pilgrims, sources of travel information, and, occasionally, depots for trade goods. A number of monasteries on the Silk Roads, especially those at Dunhuang, were institutions at which linguists translated Buddhist scriptures from Sanskrit to Chinese and other languages.

Some monasteries became great educational institutions, the leading universities of their times. The great monastery and university of Nalanda in Bihar, India, has been called the Harvard and Princeton of early medieval South and East Asia. Thousands of students from Japan, Korea, China, Southeast Asia, central Asia, Sri Lanka, and India traveled to Nalanda. It is reported that

in the eighth century, Nalanda housed about 10,000 student monks.

In its early centuries in China, Buddhism was a monastic religion. When Buddhism arrived in China, one of the first things established was the White Horse monastery. After the fall of the Han dynasty, Buddhism began to make serious inroads into Chinese culture, and many royal Chinese converts favored the religion by founding monasteries and endowing them with land and peasants to cultivate it. Over the centuries, Chinese Buddhist monasteries became wealthy, and many Chinese men and women flocked to the monasteries, escaping the taxation and labor burdens imposed by the state. In 842, in a paroxysm of antiforeign sentiment, the Tang dynasty proscribed Buddhism and other “foreign” religions. It is reported that in the persecution thousands of monasteries were suppressed and hundreds of thousands of monks defrocked (returned to civil life).

The earliest Christian monasteries grew up in the Egyptian desert toward the end of the third century. Christian monasteries had many similarities to Buddhist monasteries, but Christian monasteries were more often self-supporting instead of depending on alms from the laity. Christian monasteries were retreats from the profane world for the devout.

Christian monasteries had somewhat the same function in Christian societies as they had in Buddhist societies. Their basic role was to pray for the welfare of their society, but they also took on other roles. After the collapse of Roman authority in western Europe, the monasteries became the refuge of learning and the source of much education. Monasteries trained the officials who staffed the bureaucracies of the new European states. In the monasteries, monks laboriously copying ancient texts preserved some of the learning of classical civilizations. Monasteries were established in pagan areas to convert the people.

Some Christian monasteries, like their Buddhist counterparts, became wealthy from gifts of land and peasants. In the early medieval age, monasteries were a central element in the religious, political, and economic lives of their host societies.

—Wilfred J. Bisson

Early Medieval Buddhist Monasteries

Although monasteries may have existed prior to the emergence of Buddhism and Jainism, those two faiths have the oldest continuing monastic tradition of any religion. Both Buddhism and Jainism, which originated about the middle of the first millennium BCE, were primarily monastic creeds from their beginnings. They taught that in order to achieve enlightenment or salvation it was necessary for the believer to renounce ties to the mundane world, including especially family, and devote himself to acquiring merit. Buddha’s early followers were wandering ascetics, begging for their sustenance from pious laypeople during most of the year, but when the rainy season came they gathered in communal establishments to wait out the weather. In time, this custom of living in communal establishments extended from just the rainy season to encompass the rest of the year, and communal life in fixed abodes became the norm. This was the origin of the Buddhist monastery.

During the eight or nine centuries, from the emergence of Buddhism to the period under discussion, Buddhist monasteries had become numerous and powerful in India. (Note: The chronology of early Buddhism is a subject of controversy.) By the beginning of the early medieval age, Buddhist monasteries had established themselves in central Asia, China, and Southeast Asia, and in the next centuries they would be planted in Korea, Japan, and Tibet.

Both men and women were members of (usually, but not always separate) Buddhist monasteries. Monks (*bhikkus*) were more numerous than nuns (*bhikkunis*), and the *Vinaya* (compilation of monastic rules) specified that bhikkunis should be deferential to bhikkus. Bhikkunis were subject to many more rules than were bhikkus. Both male and female were enjoined to live chaste lives, to have only a few personal possessions, to be modest, and to be moderate in all appetites. The principal duty of monastics was to accumulate merit by living lives of purity, prayer and meditation, and, especially among the Mahayana, the extension of compassion to all sentient beings.

The Vinaya limited monks and nuns to one meal a day, usually eaten before noon. In India and Southeast Asia monks and nuns were expected to get their food by begging, and it was the obligation of laypeople to give them food. A monastic was required to eat whatever was given him, with the exception of meat if the monastic thought that the animal was killed specifically to feed him. In China, Korea, Tibet, and most of Japan, begging incurred negative social sanctions, so in those lands food was given to the monasteries in bulk and prepared (usually by laymen) in the monastic kitchens.

Many Buddhist monasteries operated schools for the laity, and some, such as Nalanda and Takashila, were famed throughout the Buddhist world of India, Southeast Asia, East Asia, and central Asia as leading institutions of higher education, universities that were the early medieval equivalent of Harvard or Oxford. Buddhist monasteries, especially in central Asia and elsewhere on the Silk Roads, often served as hostels for traveling merchants and pilgrims. Monasteries on the Silk Roads also are said to have been more directly involved in trade, sometimes serving as depositories for trade goods and perhaps assisting in the transfer of funds and payments. Buddhist monasteries, located as they were throughout the eastern half of the Eastern Hemisphere, formed a network of communication and intelligence sharing, more dependable than any system of diplomatic couriers of the time.

For several centuries in the middle of the first millennium CE, Buddhist monasteries were the locus of great political power in several Asian countries. Buddhist doctrine served to legitimate rulers, and rulers reciprocated by granting monasteries land and privileges. In China and throughout the rest of East Asia, monasteries were supported by grants of land and the enserfed peasants who worked it. These monastic estates, both land and serfs, were exempt from taxation, as were the monastics who were supported in this way. Monks who went as missionaries to new states, such as Korea's three kingdoms, Japan, or the kingdoms of Southeast Asia, frequently served as advisers to the ruler and staffed the nascent bureaucracy of many lands.

The eighth century witnessed the climax of the political power of the Buddhist monasteries in some East Asian states. In the eighth century, Buddhist monasteries that surrounded Nara, Japan's early capital, grew so powerful that Emperor Kammu moved the capital to Heien (Kyoto) in 794 to escape their tutelage. In the succeeding centuries, some Buddhist monasteries in Japan and elsewhere maintained private armies, sometimes consisting of armed monks. Toward the end of the first millennium CE, armed monks repeatedly intervened in the political affairs of Heian, Japan's capital.

In China in the ninth century, the last of the Tang dynasty, a severe backlash against the power of Buddhist monasteries nearly destroyed Buddhism in China and permanently diminished its influence there. By the 840s, Buddhist monasteries had, collectively, become the largest landlord and the most potent economic force in China. The monasteries' control of great estates and numerous serf-peasants effectively removed these estates from the tax rolls and the peasants from those available for conscription for *corvée* labor or military service. Likewise, the monks were exempt from state labor and military service. Buddhism was charged with being a foreign religion, incompatible with Chinese culture. It was declared an antisocial religion, and the monks' celibacy was deemed antithetical to the filial piety demanded by Chinese mores. From 841 to 845, a thorough and savage persecution of Buddhism (and other "foreign" religions) resulted in the confiscation of many monastic estates, the defrocking and returning to lay life of more than a quarter of a million monks, the freeing of hundreds of thousands of monastic slaves, and the consequent swelling of the tax rolls. Although the persecution ended in 845, Buddhist monasteries never regained their previous position of power and influence in China.

In India, Buddhist monasteries were most influential in the northwest and the northeast. These were the areas that would, in the second millennium CE, become strongly supportive of Islam. In these areas, Buddhist monasteries received great patronage of the rulers, especially the Pala dynasty of Bengal (750–1174). The Pala dynasty, although centered in Bengal, in the first

half of the ninth century controlled a vast swath of territory reaching across northern India to what is now Afghanistan. Wherever its rule prevailed, Buddhist monasteries prospered. The most important of these monasteries was Nalanda, on which the Pala kings lavished land and favors. In the tenth century, local Hindu regimes ousted the Palas from most of their territory except that in the northeast: Bengal and Bihar. With the Palas went the royal patronage for the Buddhist monasteries. In 1174 a Hindu dynasty, the Senas, overthrew Pala power in Bengal, and royal patronage of Buddhist monasteries in India ended.

But already, in the beginning of the eleventh century, Muslim rulers from Afghanistan, starting with Mahmud of Ghazni (973–1030), had been leading marauding raids into western India, sacking Hindu temples and Buddhist monasteries. As Muslims, they had a special abhorrence for monasteries and not only destroyed the buildings but also killed many monks. By the end of the twelfth century the Muslim raiders had conquered most of northern India. In 1193 a Muslim force destroyed Nalanda and massacred thousands of monks, burning some alive. Buddhist monasteries, and with them the Buddhist religion, disappeared from India.

Buddhist monasteries continued to thrive, however, in other lands. Tibet was a closed Buddhist theocracy governed by Buddhist monks until the communist invasion in 1950. Buddhist monasteries and nunneries still flourish in most of Southeast Asia and Sri Lanka, and they still exist in China, Korea, Japan and Vietnam.

Christian Monasticism to 1000 CE

During the late antique and early medieval periods, Christian monasticism grew from a marginal movement into an integral and important element in both West European and Byzantine society. While the term “monasticism” is commonly used to refer to the pursuit of communal religious life in a monastery or nunnery, a variety of the devotional practices that developed between the third and tenth centuries can be called monastic. Not all of these practices involved individuals living in common, but they did share certain traits: a highly structured life centered around prayer and religious meditation, abdication of personal ownership of property, restriction of bodily desires through voluntary celibacy, fasting, physical discipline, and a desire to retreat from the secular world.

Monasticism was not a Christian invention. It was an important element of Buddhist religious practice for at least three centuries before the time of Christ, although Buddhist monks and nuns tended to be more closely tied to surrounding lay communities than had the earliest Christian monks. While there is not direct evidence that Buddhist monasticism directly influenced the development of Christian monasticism, it may have done so indirectly through the incorporation of Buddhist ideas into Manichaeism. The Manichaean elect lived an ascetic, monastic life, and Manichaeism still had a firm presence in Egypt at the time that Christian monasticism began there. The main influences on the early development of Christian monasticism, however, appear to have been New Testament accounts of the lives led by the first Christians and a tradition of Jewish asceticism as exemplified by the Nazirites, the Essenes, and the “Therapeutae” described by Philo of Alexandria (20 BCE–50 CE).

Christian monasticism began in the deserts of Egypt in the late third century CE. The earliest practitioners of monasticism did not generally congregate in communities: although some monks did live near each other, with younger monks frequently gathering around an older, more experienced monk who served as an adviser and teacher, devotional pursuits were car-

ried out privately and individually. Although not the first of the desert ascetics, Antony of Egypt (d. 356) was the most famous and influential and attracted a large number of disciples. One of these disciples, Pachomius (ca. 290–346), organized the first formal monastic communities and may have also written the first set of monastic regulations, or rules. In a typical Pachomian monastery, monks or nuns would each have their own cells, but they would gather for meals, prayer, and communal labor, generally cloth or basket weaving. Property was held in common, and food and clothing were distributed from a central storehouse. Another of Antony's disciples, Hilarion (ca. 291–371), introduced monasticism to Palestine. By the mid-350s, Basil of Caesarea (ca. 330–379) was able to make a tour of established monastic communities in Egypt, the Levant, and parts of what are now Syria, northern Iraq, and eastern Turkey.

Basil himself became a monastic leader, and his *Rule of St. Basil* eventually became the basis of monastic life in the majority of monasteries in the Greek East. Eastern monasticism placed a heavy emphasis on prayer and the frequent repetition of the liturgy. Some monasteries, such as the Studeon in Constantinople, were even organized to provide perpetual prayer, with the monks divided into shifts so that a group was always praying at any given hour of the day or night. Basil's *Rule* allowed for a variety of institutional structures for the monastic life, and throughout the Byzantine period tight-knit enclosed monasteries coexisted with communities of isolated cells spread around a common meetinghouse and individual ascetics, some of whom attracted large followings. Monastic communities for women were also popular, although they tended to be much more closely regulated and regimented than male communities. While withdrawing from the secular world was one of the main goals of Eastern (and Western) monasticism, monks in the Byzantine empire frequently became involved in the theological disputes of the Greek Church. It was not unheard of for mobs of monks to demonstrate and even riot during the various early medieval debates over Christology, and the Iconoclast Controversy of the eighth century saw widespread imperial persecution of iconophile monks.

Saint Benedict of Nursia (480–547) prays with monks. Fresco from the Abbey of Monteoliveto Maggiore Siena, about 1500. (The Art Archive/Corbis)

Monasticism first began to spread to the Latin West in the middle of the fourth century. Martin of Tours (ca. 316–397) founded a monastic community near Poitiers around 360 and another near Tours after he became the bishop of that city in 371. Martin's monasteries followed the Egyptian model, with Martin and his disciples living and praying in separate cells. Egyptian monasticism was also the inspiration for John Cassian (ca. 365–ca. 435), who wrote two manuals (the *Institutes* and the *Conferences*) that would heavily influence later Western monastic writing. Cassian's contemporary, Augustine of Hippo (354–430), established communities of both men and women in his diocese and lived a monastic life with his cathedral clergy. Augustine's writings on the monastic life would prove influential in forming what would later be called the Augustinian Rule, but the first formal monastic rules in the Latin West were actually written by Caesarius of Arles (ca. 468–542). While Caesarius's rule for monks was eventually superseded by that of Benedict of Nursia (ca. 480–ca. 550), his rule for nuns remained popular for several centuries.

Benedict originally wrote his rule for the monastic foundation at Monte Cassino in Italy (established ca. 520). The *Rule of St. Benedict* envisioned monasteries in which monks lived,

➤ RULE OF ST. BENEDICT

When St. Benedict wrote his *Rule* in the mid-sixth century CE, there were many varieties of monastic life. In the first chapter of the *Rule*, Benedict describes four types of monks:

“The first is that of the cenobites, that is the monastic, serving under a rule and an abbot. The second kind is that of the anchorites, that is the hermits, those who have learned to fight against the devil not by the new fervor of a conversion but by a long probation in a monastery. . . . [T]hey are able, God helping them, to fight with their own hand or arm against the vices of the flesh or their own thoughts. But a third and very bad kind of monk is that of the sarabites. . . . Being shut up by twos and threes alone and without a shepherd, in their own and not in the Lord’s sheepfold, they have their own desires for a law. For whatever they think good and choose, that they deem holy. . . . But the fourth kind of monk is the kind called the ‘wanderers around’ (gyrovagi). . . . [T]hey are always wandering and never stationary, serving their own pleasures and the allurements of the palate, and in every way worse than the sarabites.”

—Stephen Allen

Francis E. Peters, *Judaism, Christianity, and Islam: The Classical Texts and Their Interpretation* (Princeton, NJ: Princeton University Press, 1990), 152.

worked, and prayed in common under the leadership of an abbot, to whom complete obedience was due. Monks were expected to be chaste, to remain in the monastery at all times (except for special circumstances), and not to own any private property. Specific hours were scheduled for work and prayer, and the rule also went into great detail about diet, the distribution of monastic goods, sleeping arrangements, provisions for the ill and elderly, and other aspects of daily communal life. The *Rule of St. Benedict* grew in popularity slowly in the first few centuries after it was created, gaining some impetus from the favor of Pope Gregory I (ca. 540–604). Emperor Charlemagne (ca. 742–814)

and his successors attempted, with some success, to impose the Benedictine rule on all of the monasteries in his realm, and by the end of the tenth century Benedictine monasticism had become the dominant form of monastic life in western Europe.

A distinct form of monasticism, perhaps also influenced by Eastern practices, developed in Ireland in the fifth century and was spread by Irish missionaries to northern Europe and eventually into Gaul and Italy, where for a time it competed for popularity with the Benedictine system. Irish monasticism was often closely tied to secular politics, with monastic and lay leaders generally being closely related. Irish monks often practiced extreme asceticism and harsh physical discipline, and the concept of being an exile for Christ (a missionary who vowed never to return home) was a popular one. By the end of the tenth century, however, the Irish form of monasticism was mainly limited to Ireland proper and some parts of the British Isles.

Nalanda—An International Buddhist Center of Learning, 500–1200 CE

The Buddhist monastic site of Nalanda is located about 55 miles southeast of present-day Patna, India, in Bihar Province. The name “Nalanda,”

sometimes translated as “lotus,” is thought to reference the many ponds that were recorded as surrounding the site. Other possible derivations of the site’s name include a reference to the historical Buddha’s previous life, in which as King Nalanda he established his domain in this region. Nalanda was an active site of Buddhist scholarship from the fifth century to the twelfth century, although evidence of Buddhist activity in the area dates from the time of the historical Buddha Sakyamuni. Historically Nalanda was linked to the nearby royal city of Rajagrha. Rajagrha was the site of the famous “taming the wild elephant” story, one of the Eight Great Wonders of the Buddha’s life, in which a jealous monk incited an elephant to charge the historical Buddha. Rather than killing the Buddha, as the inciter had hoped, the elephant knelt before the Buddha in homage.

Nalanda as a teaching center or university is recorded in a wide variety of records including travelogues by famous pilgrims to the site, notably the Chinese pilgrims Xuanzang and I Ching, as well as within the sutras themselves. The Mahaparinirvana Sutra details the historical Buddha’s visits to Nalanda, often stopping at a nearby mango grove to give teachings and debate with the nonbelieving Brahmins. Xuanzang notes that the mango grove site was eventually bought and donated to the Buddha by 500 nearby merchants, upon which the Buddha stayed at the site for three months teaching. Ananda, one of the Buddha’s greatest disciples, argued for Nalanda as the site of the Buddha’s eventual *parinirvana*, preferring it to the site of Kusinagara, which had already been chosen by the Buddha. Several hundred years later the historical Buddha’s activities at Nalanda were commemorated with a temple built in honor of his follower Sariputra by King Asoka.

Nalanda became a great center of Buddhist learning only centuries after the Buddha’s passing. Legend has it that the site was chosen by two brothers seeking to make Nalanda once again a center of learning. Originally composed of eight temples, Nalanda quickly gained in size and prominence. The legend continues that 500 masters who came to Nalanda after the initial construction phase brought with them the entire Mahayana canon as well as additional sutras

Ruins of Nalanda in present-day Bihar, India. Nalanda was a university and Buddhist center that dates back to at least the fifth century BCE. During the Gupta dynasty, support of the kings allowed the university to expand, and it was a prime destination for scholars and Buddhist pilgrims. (Lindsay Hebbard/Corbis)

that had by then been committed to writing. Nalanda henceforth became the central repository for Mahayana texts in Asia, a fact that prompted the long and arduous pilgrimages to the site of devout clergy and laypeople alike.

Enjoying extensive and ongoing royal patronage from the Gupta dynasty (240–550 CE) and the Pala dynasty (750–1179 CE), Nalanda’s reputation for study of not only Buddhist texts and theories but also Sanskrit, logic, and competing schools of thought created a center of international renown. Nalanda produced a long list of illustrious Buddhist masters, examples of which form a veritable who’s who of famous Buddhist masters including Nagarjuna, whose lineage was carried on by Aryadeva and Asvaghosa as well as Asanga and his brother and follower Vasubandhu, author of the *Abhidharmakosa*. From the lineages of Nagarjuna and Asanga stem the two major Mahayana philosophical schools of Buddhism, Madhyamika and Yogacara. The teachings from these two main schools of thought were then widely distributed across Asia by the student pilgrims upon returning to their respective homelands.

Descriptions of the Nalanda site come largely from records left by the Chinese pilgrim Xuanzang (599–644 CE), who arrived at Nalanda in 637 and stayed for two years. By the time of Xuanzang’s arrival, Nalanda had grown into an international center of learning, with students

➤ XUANZANG, CHINESE BUDDHIST PILGRIM TO NALANDA

Much of what is known about Nalanda during its heyday is due to the extensive writings of the Tang dynasty monk Xuanzang (599–644 CE). Defying an imperial decree, he left the Chinese capital of Chang'an in 629. Heading west along what has come to be known as the Silk Roads, he traversed some of the most dangerous routes of his time, braving desert and bandit alike to cross central Asia on his way to India. Throughout his journey, he recorded the great sites of the region, many of which are still extant today. After his arrival at Nalanda, he became the disciple of Silabhadra, abbot of Nalanda, and was initiated into the Yogacara lineage. Xuanzang's 16-year journey through central Asia and India in search of the Buddhist teachings was immortalized in the Ming dynasty epic saga *Journey to the West* (*Xiyouji*). Upon his return to China in 645, Xuanzang set about translating into Chinese the numerous scriptures he had brought back from India. He also brought back Buddhist relics and statues, which together with the scriptures were housed in the Great Wild Goose pagoda. Today a bronze statue of Xuanzang presides over the pagoda complex in Chang'an, present-day Xian.

—Karil J. Kucera

arriving from all over Asia. Xuanzang remarked not only on the physical attributes of Nalanda but also on the ritual activities occurring at the site. Marveling at the extensive size of Nalanda, at one point housing 8,500 students, Xuanzang also noted the beauty of the site, describing in detail the extensive sculptural program undertaken at Nalanda. Thanks to the support of the Gupta

kings, Nalanda benefited from the finest artisans money could buy to decorate the hundreds of buildings and shrines found there. The extensive library housing the Abhidharma and Mahayana texts was described by the Chinese pilgrim Yijing as a “four-square, like a city. There are four large gateways of three stories each. Each story is some ten feet in height. The whole is covered in tiles.” In addition to the library, other monuments found at the Nalanda site included numerous stupa housing the relics of the historical Buddha as well as those of two of his famous disciples, Sariputra and Maudgalyayana, both of whom were born not far from Nalanda and were said to have entered nirvana at Nalanda.

The Nalanda complex thrived from the fifth through the twelfth centuries, falling into ruin after the arrival of the Muslim invaders of India. The last of the Pala kings who succeeded the Gupta line in patronizing Nalanda's scholarship was King Govindapaladeva, who died in 1197. Soon after the site was ransacked and destroyed by the Muslim leader Muhammad Bhakhtyar Kalji (1197–1206), who purportedly would have spared Nalanda if the library had contained a copy of the Quran. Although visited periodically by pilgrims over the next half century, Nalanda would slip into oblivion until rediscovered in the nineteenth century by British archaeologists. Positive identification of the site came in the form of excavated seals bearing the name of Nalanda.

■ Introduction: Mysticism

Most early medieval religions had a component of mysticism. Mysticism has been defined as a teaching, an experience of seeking an intuitive knowledge or even

union with the deity, or an experience of reality not rooted in logic, reason, or sensual experience. Epistemologically, mysticism is a way of knowing by experiencing an inner or transcendent reality.

By another definition, any deeply emotional religious experience is a mystical experience.

Mysticism pervaded early Christianity. The deep involvement of the Christian mass, the reenactment of Christ's passion with the culminating consumption of Christ in the Eucharist, is, to the devotee, the union or oneness with God. The union with God is the essential mystical experience of both Eastern and Abrahamic (Judaism, Christianity, and Islam) religious traditions. Early Christians sought mystical experiences also by asceticism, suffering cold and pain, renouncing sex, and sometimes starving themselves to find God. In the third century, many Christian mystics became hermits in the Egyptian desert to endure suffering as Christ suffered. This was their way of finding oneness with God.

Adherents of Eastern religions also sought salvation by embracing asceticism. For them, renouncing the pleasures of this world was aimed at release from the entanglements of the mundane world. Buddhists sought to attain release from the mundane world by deep meditation (*jhana*) that leads to a state of bliss.

In about the sixth century CE in southern India, *bhakti* devotionism led to particularly emotional mystical experiences. In *bhakti*, the devotee seeks to express his (or often her) love for the deity through chants, songs, and other ways. Another Indian mystical movement was *tantra*, which had both Hindu and Buddhist followers. Tantricism pervaded the Mahayana Buddhism of Bengal as well as that of Tibet.

Sufi is the most recognized form of mysticism among Muslims. Though the greatest development of Sufi took place after this era (300–1000), the origins date to the ninth century or even earlier.

In the seventh century, many Orthodox Christian monks fled the Muslim conquest of Egypt to find sanctuary on Mount Athos, or the Holy Mountain, a peninsula in northern Greece. Many monasteries were established on the Holy Mountain, and the monks developed the tradition of *hesychasm* in which the monk establishes a direct union with God through prayer and other devotional practices.

Mystics have often been a problem for organized religions. Since mystics seek and claim to

experience a direct knowledge and even union with God, they have little use for priestly hierarchies and institutions that seek to serve as mediators between God and the believer. Mystics are often disdainful of elaborate theology or religious law, claiming that their direct experience with God makes the law irrelevant. They are sometimes accused of thinking themselves above the law. They have often been persecuted and sometimes martyred by religious authorities.

—Wilfred J. Bisson

Early Hindu Devotional Mysticism

Devotional worship in South Asia is called *bhakti*, a word meaning “enjoyment,” implying that the devoted follower enjoys a share of his or her deity's blessings. For the devotee, this world is itself a gift from god. It is a manifestation of grace; sometimes the world is even the body of god. Devotion is a form of religion often expressed through heightened emotions of love or of longing. As a result, God in these traditions is often portrayed in image and story in personal terms rather than in abstract philosophical terms or as a formless Brahman. Emotionalism is a means of experiencing God, in seeing God in all things or in oneself. It is through the realization of the role of God in all things that one achieves the soteriological goal of liberation through devotion.

The predominant *bhakti* traditions center on the god Vishnu and his various incarnations, especially Rama and Krishna. Krishna in particular is presented in a rich array of literary narratives that support his worship through stories of his life and exploits in the *Harivamsas*, the *Vishnu Purana*, and the *Bhagavata Purana*. These stories portray Krishna as a mischievous youth, destroying demons and engaging in amorous exploits. These narratives become a source for the devotee's experience of the Lord, as the devotee can imagine himself or herself in the role of characters in the story or can experience the deeds of the Lord in a familiar geography now made sacred by devotion.

From the sixth through the ninth centuries CE the Alvars of southern India developed a prominent form of Vaishnava devotion (followers of Vishnu, his spouse Shri or Lakshmi, and

other figures related to Vishnu). They expressed a deeply personal and emotional form of devotion through their poetry. Writing in Tamil, their verses use a rich system of natural images and scenes as metaphors to express their devotion. Sometimes this poetry expresses a heightened sense of God in all things. An important characteristic of this poetry, however, is pained longing as a result of feeling separated from God, a form of devotion known as *viraba bhakti*. In particular, Nammalvar (ca. 880–930), the most famous of these poets, wrote of the dual nature of Vishnu as both a transcendent being, lacking form or quality, and yet also present in temples and icons dedicated to him, locating the Lord within the context of Tamil geography. By the tenth century CE, the theologian Nathamuni had collected the works of the Alvars in a volume titled *Nalayira Divya Prabandham (Four Thousand Divine Compositions)*. This text, regarded in southern India as a Tamil equivalent to the Sanskrit Vedas, was foundational for the Shri Vaishnava sect.

Much of the theology of bhakti is the result of the work of Ramanuja (ca. 1017–1137), an early proponent of the emerging Shri Vaishnava movement. His philosophy was that of *Vishishtadvaita* (modified nondualism), which contrasted with the monistic Advaita Vedanta of Shankara in which the world is merely appearance, a manifestation of impersonal Brahman. Ramanuja's vision was theistic: God is a personal being, and the world and everyone in it are entirely dependent upon Vishnu. Since the world is the body of the Lord, it is not simply appearance but rather an expression of God's glory. Liberation is the experience of union with the Lord and is a result of the total surrender (*prapatti*) of the devotee. This surrender led to liberation from rebirth and union with Vishnu in his heaven, Vaikuntha.

While the most prominent devotional sects focused on worship of Vishnu and his incarnations, bhakti was a component of all sectarian traditions. The Shaiva Siddhanta sect propounded a particularly theistic view of the god Shiva. In this sect, the individual soul is distinct from God and has become entangled in the physical world by karma. One could purify oneself through daily devotional rituals, entering a

state of union with Shiva at death. Despite an adherence to the belief in a fundamental distinction between the individual and Shiva, the Shaiva Siddhanta was to influence later forms of nondual Tantric Shaivism.

This period saw the rise of prominent goddess (*devi*) traditions as well. Goddess worship cuts across the spectrum of mystical practices, popular devotion, and Tantric sects. In many, the goddess is equated with the physical or natural world or is the dynamic power (*shakti*) underlying phenomena. While this creative power is sometimes identified as the Supreme Being, at other times shakti is identified as the manifestation of the abilities of masculine gods. For example, the *Devi Mahatmya* (found in the *Markandeya Purana*, dating from between the fifth and seventh centuries CE), portrays the goddess Durga as a powerful warrior, created from the combination of the powers of Shiva, Vishnu, and other gods. Paralleling this story, the goddess Kali appeared among emerging Tantric sects in Bengal in the seventh and eighth centuries CE as a ferocious, bloodthirsty goddess, associated with cremation grounds and portrayed as trampling the inert corpse of Shiva. The Shri Vidya tradition likewise identifies the goddess as the Supreme Being, closely identifying her with the sound that underlies the cosmos and invoked through mantra recitation. In this tradition, one performs meditation with mantras evoking the goddess as well as through the use of geometric diagrams (*yantra*) whose symbolism aids in visualizing the nature of the goddess.

Devotion is a powerful tool for spiritual development. Even Patañjali's *Yoga-Sutras* express the necessity of devotion to the Lord as a means of focusing one's attention in meditation. Most forms of Hindu mysticism rely on meditating on a deity. The emotional and even ecstatic states that the devotee found himself or herself in served to keep their attention solely on the Supreme, even when the god or goddess of one's devotion was to be found shining through the everyday world.

Buddhist Mysticism

Buddhist mysticism ostensibly aims to achieve nirvana, the extinction or cessation of suffering, as the Buddha taught in his sermon on the Four Noble Truths. In this context, the fourth Noble Truth lays out calming (*samatha*) and insight (*vipasyana*) forms of meditation to achieve this goal. Put more positively, however, Buddhist meditation seeks to achieve an insight into the true nature of reality, to achieve that state of awakening (*bodhi*) that dispels ignorance. Mahayana Buddhism expresses this as a state in which one has insight into the true nature of reality or to achieve a complete union with the transcendent.

The most thorough early treatment of Buddhist mystical practice was Buddhaghosa's comprehensive fifth-century CE manual, the *Visuddhimagga* (*Path of Purification*). He describes calming meditation as the achievement of states of trance, traditionally listed as eight in number, in order to quiet the mind and achieve tranquility. These states have much in common with other forms of traditional yoga. Meditation is based on focusing attention on an object of concentration, such as a colored disk. The practitioner might instead focus on one of the four immeasurable qualities: kindness, compassion, sympathetic joy, or equanimity. Buddhist texts prescribe other objects suitable for meditation as well. The breath is an important object in both calming and insight forms of meditation as well as in traditional yoga. One might visualize the Buddha, recollecting his virtuous qualities. Or one might meditate on a corpse, since awareness of one's own mortality is a profound method of achieving insight into the transience of life.

Insight meditation, on the other hand, aims to increase one's awareness by being mindful of oneself or the surrounding environment. All dissatisfaction and suffering is the result of desire: either the desire for pleasant experiences or the

➤ METTA MEDITATION

An important preliminary form of meditation in Buddhism and one described in Buddhaghosa's *Visuddhimagga* is *metta* ("kindness") meditation, by which a person develops an attitude of kindness toward all others. A person starts by imagining someone he or she already loves or feels affection for (but not passionate or romantic love). By meditating on that person, he or she establishes the feeling of *metta*. With this feeling in mind, a person begins to meditate on people he or she is not as kindly disposed toward and even people he or she dislikes. Through practice, a person learns to radiate an attitude of kindness toward everyone without distinction.

—Matthew Bingley

desire to avoid unpleasant experiences. Mindfulness was thus the practice of increasing awareness while decreasing the desire to respond, and Buddhist meditation manuals such as Buddhaghosa's noted that this was, strictly speaking, the only essential method for achieving nirvana.

The monastery (*vihara*) was the traditional center of the Buddhist community (*sangha*). Like other forms of Indian mysticism, ordination entailed renunciation of possessions, property, wealth, and relationships. The novice monk or nun was expected to shave his or her head as a symbol of renunciation and to possess only what was given freely as a donation. Monks were expected to complete daily begging rounds for food, and a common term for a Buddhist monk was "beggar" (*bhikshu*). Each month, recitation of the rules of monastic discipline (*vinaya*) reminded monks of the rules they must follow.

The complex relationship between monastic and lay institutions was premised on a reciprocal relationship. The laity supported monasteries with offerings of food, gifts, and donations for construction, and the monasteries in turn provided spiritual guidance and education for communities. Royal patronage often ensured the maintenance of monastic institutions, although by the mid-first millennium CE royal patronage of Buddhist institutions in India declined, while support for Hindu institutions increased. An exception is in northeastern India, where the Pala

dynasty supported monasteries from circa 750 CE onward. Of singular note was the Buddhist center at Nalanda in present-day Bihar, the foremost educational and monastic institution of its time, where a number of influential Buddhist doctrines developed. Founded in the fifth century CE, at its height it held perhaps 10,000 students, and its destruction in 1193 marked the demise of Buddhism in the land of its birth.

Later Mahayana commentators criticized the monastic ideal as too conservative and patriarchal and argued that laypersons could follow the Buddhist path as well. A proliferation of meditative practices and devotional worship of Buddhist divinities accompanied this tendency among Mahayana followers to universal Buddhist soteriology. The monastic ideal persisted, however, in many Mahayana Buddhist settings outside of India, such as Zen in East Asia, as well as in Tibet, where monasteries also held immense political power until the twentieth century.

The bodhisattva ideal of Indian Mahayana meant a shift in the understanding of Buddhist meditation. Mahayana developed a system of stages (*bhumi*) to attain through lifetimes of practice as the bodhisattva pursued full Buddhahood. In the eighth century Kamalashila's *Bhavanakrama* (*Stages of Meditation*) described meditation as a means to better achieve wisdom and aid other beings in the path to nirvana. These perfections are qualities that one cultivates in oneself, and typically listed as six: generosity, good conduct, patience, vigor, meditation absorption, and wisdom. The sixth quality, the perfection of wisdom, was of central importance because at this stage, the bodhisattva realizes the ultimately empty, illusory, and unified nature of reality, an experience of awakening.

Esoteric Buddhism, or Vajrayana, is a form of Tantra that, like its Hindu counterpart, emphasizes secret initiation and teachings and ritual identification with a divine being. One major difference from Hinduism, however, is that Vajrayana occurs within a Buddhist soteriological framework that emphasizes distinct doctrines such as nirvana, no-self, and emptiness. In Vajrayana meditation, the practitioner identifies with a particular Buddhist deity through chanting man-

tra (sacred formulae) while meditating on a mandala (a symbolic representation of the Buddhist cosmos) or visualizing the deity and accompanied by ritual hand gestures (*mudra*). One thus achieves awakening by assuming the qualities of an awakened being through achieving a state of union with a Buddha or bodhisattva. Vajrayana practices are attested by the seventh century CE in India. From the efforts of Buddhist missionaries such as Padmasambhava (ca. eighth century CE), Vajrayana became established as the dominant form of Buddhist practice among the sects of Tibetan Buddhism.

Mysticism in South Asia

Mysticism in South Asia generally aims at attaining liberation or release (*moksha*) from the suffering of repeated rebirth as a result of accruing karma. In the period 300–1000 CE several of the major schools of mysticism developed. The first was yoga (“union” or “discipline”), classically presented as distilling the pure spirit from entanglement with the body. A second line of thought was Vedanta (“end of the Vedas”), which is based on metaphysical speculation in the *Upanishads* equating the essence of the cosmos (*brahman*) with one’s eternal and true self (*atman*). In this period we also see the rise of Tantric sects apart from the orthodox schools that purport to rely on the Veda.

Dating from the third century CE the Yogasutras of Patañjali present the most cogent source for the classical practice of yoga. Yoga as a method aims at the “cessation of fluctuating

thoughts” (YS 1.2), a state in which the spirit (*purusha*) reveals itself in its innate nature as pure witness, isolated from matter (*prakriti*), a metaphysical view found in the Samkhya school. When one experiences pure spirit freed from attachment to matter, one is liberated.

Patañjali’s program is called Eight-Limbed (*ashtanga*) yoga. This form of yoga involves a progressive withdrawal from outward activity to focus on finding the pure self hiding deep within. The first two of these limbs are moral restraints and observances. The moral restraints include practicing nonviolence, honesty, and celibacy; refraining from stealing; and avoiding greed. The observances include cultivating purity, contentment, austerity, self-study, and devotion to the Lord. The third limb is the most visible form of yoga today: control of physical posture (*asana*). This is commonly known as *batba* yoga and involves conditioning the body’s flexibility to rest comfortably in a variety of positions. The fourth limb is breath control, using the breath as a method of developing concentration and increased control facilitates quieting the mind. The fifth limb is withdrawal of the senses, disengaging the mind from the outside world for better introspection. The sixth limb is concentration. The yogin fixes attention on a single object for sustained periods of time. The seventh limb is the meditation (*dhyana*) during which the yogin’s attention is absorbed into a single point or object. The eighth limb is the trancelike state of intense concentration called *samadhi* at which point the mind is completely stilled. At this point consciousness is experienced in its true nature as spirit (*purusha*).

During this era, Shankaracarya (ca. 780–832 CE) developed Advaita Vedanta as an interpretation of the metaphysical idealism of the Upanishads. In contrast to the polarity of matter and spirit found in Samkhya and Yoga, Shankara taught a form of monism or nonduality (*advaita*). This reality is Brahman, the essence of the world and the self (*atman*). The world in all its diverse forms, every object one perceives, and even the variety of people in the world are all merely appearance. They are reflections, or manifestations, of Brahman, which alone is truly real. Later philosophers of Vedanta often reacted

➤ MAGIC POWERS

Patañjali’s *Yoga-sutras* present various magical powers (*siddhi*) that occur in connection with various meditations. These powers derive from deep contemplation on an object. For example, the *Yoga-sutras* claim that through meditation on the relation between the body and space, a person can levitate. Other powers include the ability to read minds, to become invisible, to have visions, and to hear things far away. But while Patañjali enumerates these and other powers, he also warns the yogin not to do yoga for the sake of gaining magical abilities because they are a distraction from the ultimate goal of achieving liberation.

—Matthew Bingley

to Shankara’s radical monism, offering more moderate approaches to nonduality that incorporated theistic elements and did not relegate the status of the world to mere appearance.

Tantric meditation (*sadhana*) is typically predicated on the divinity of the self and the correspondence between the physical body and the cosmos. Rituals and *sadhana* involve the recitation of various mantras, visualization of deities, and identification of various deities with parts of the body. These *sadhana* can be used for either identifying oneself with a chosen deity or for the sake of developing magical powers for more worldly reasons.

Even when their metaphysical beliefs are widely divergent, many of these schools of thought share similar practices. An exhaustive list is impossible due to the variety of meditative methods, bodily mortification, asceticism, etc., seen in South Asian mysticism. But a few prevalent methods stand out as unique to this milieu. Many techniques of meditation are forms of concentrating one’s attention on an object, such as the breath. Reciting a mantra, a sacred formula or chant, is another significant method. The most famous example of a mantra is the simple syllable *Om*. Closely akin to mantra is repeating praises of a deity, such as “*Om namah Shivaya*” (“*Om Praise to Shiva!*”). Other meditative practices involve visualizing one’s deity. Another

common form of meditation is visualizing the subtle channels of energy in the body. Through a combination of visualization, breath control, and mantra recitation, the meditator induces a flow of energy from the base of the spine through the energy centers (*cakra*) in the body upward to a point at a distance of 12 fingers in length above the crown of the head. This practice is called Kundalini yoga, and the union of the energy in the body with the point above the head is described as the uniting of the goddess Shakti with Shiva.

Apart from the metaphysical speculation and norms of meditative practice, mysticism in South Asia has been a reaction against the norms of social and worldly life. An important feature of South Asian mysticism is the act of renunciation (*sannyasa*). To pursue the path of spiritual liberation, one must abandon family, home, wealth, and possessions. Renunciation as a rejection of traditional caste roles is the fourth stage in traditional accounts of *dharmā*. Renunciates lead lives of homelessness, begging for food, and some gather in hermitages called *ashrama* to practice together. Also, one should not underestimate the importance placed on finding the right guru (spiritual teacher). For the novice, the guru's spiritual instruction must be obeyed scrupulously. The guru represents the body of traditional knowledge and is a living example of spiritual seeking.

The social dimensions of South Asian mysticism as well as the practices involved apply to both Buddhism and Jainism. These traditions also developed analogous modes of ascetic practice, renunciation, the need for a spiritual teacher, and the express goal of liberation from karma and rebirth.

Christian Mysticism

Mysticism in the Christian context generally refers to a believer's direct experience of God in a manner that is unusual both for the believer and for Christians. The root of the term mystical means "secret" or "hidden" and the mystical experience is usually taken to be a foretaste of the heavenly bliss that is promised to those who will be with God after death. Further descriptions tend to be idiosyncratic, as the mystic is forced to use human language to describe a unique spiritual encounter with the divine. The goal or experience of the mystic is often referred to as being in the presence of God, having a vision of God, or achieving a union—sometimes explicitly sexual—with God.

Scripture provides models for the Christian mystic. The Hebrew writings, or Old Testament, present several examples of patriarchs and prophets directly encountering God. The New Testament provides the Transfiguration of Jesus, Paul's being lifted to the Third Heaven, and John's Revelation. In the third century Neoplatonic writers such as Plotinus provided pagans and Christians alike with a philosophical model of the stages in the soul's ascent to the divine (The One) that quickly became a theological model. Both Neoplatonism and Christianity posited a separation of humanity from God, a descent or fall, that could be remedied by a conscious and concentrated effort to shed attachment to the natural world, enhance one's spirituality above all else, and direct one's spirit toward the divine source existence.

In the Greek-speaking Christian East, Alexandria served as a center for merging Neoplatonism and Christianity. Third- and fourth-century theologians such as Origen and Evagrius Pontus were important pioneers whose writings on spiritual ascent influenced later generations of both Greek and Latin speakers. At the same time, Christian men and women began abandoning the world for lives of prayerful isolation in the Egyptian desert. Their strict discipline and self-denial as hermits, or later in communities of monks, amounted to the *askesis*, or asceticism, that both Christians and Neoplatonists taught was necessary for the soul's ascent. Indeed, many of these earliest monks—

the Desert Fathers and Mothers—experienced God, especially the Holy Spirit, in ways that could only be described as mystical. Thus, by the mid-fourth century Christianity had a firm foundation in both mystical theology and the practice of mysticism in the monastic setting.

In the Latin West, Ambrose of Milan and his pupil Augustine of Hippo translated and further developed the Christian mystical tradition. Ambrose, bishop and teacher of Augustine, embodied much of his mystical understanding in his commentary on the biblical Song of Songs. Its allusions to sexual ecstasy and alcoholic intoxication had to be taken allegorically, and Ambrose turns these toward an ideal of asceticism, virginity, and the experience of Christ in the sacraments. Augustine, bishop of Hippo in later life, absorbed Ambrose's ideals and first sought the monastic life within which to practice them. He believed that the true mystic could only live as a monk, although every Christian has the goal of divine union. In his *Confessions* he recounts his own mystical experiences, and in other works he develops the theology behind their possibility: humans are made in the divine image and only with God's invitation and grace can ascend. As a pastor, though, he also followed Ambrose in linking true divine experience with the Church and its sacraments. The contemplative life begun on earth will be fulfilled and perfected in heaven.

At about the same moment, John Cassian, a monk from Romania, was translating his experience in the Egyptian desert to southern Gaul. At his new monastery near Marseilles he stressed the linkage of renunciation (of the world's appeal, former vices and desires, and worldly things) with the unceasing fire of prayer. Together these would lead his monks to a vision of God and conjunction with the divine, although the path was difficult. He wrote of his mystical understanding in his *Conferences* and his *Institutes*, which became instant classics of monastic spirituality. The later founder of mainstream Western monasticism, Benedict of Nursia, praised the two works, although he expected little in the way of such fire from his monks. Even so, monasticism would continue to host such mysticism as there was in the early medieval West. Pope Gregory I, a huge fan and biographer of Benedict, spread the message of monastic contemplation of God, although he

Saint Augustine of Hippo is considered by many to be the greatest of the Latin church fathers. Augustine's influence extended from late antiquity into the early Middle Ages and beyond. In common with many mystics, Augustine believed that a direct relation with God was utmost, and earthly power and pomp was unimportant. Augustine spoke of an internal and subjective "City of God," a holy community of believers. (Library of Congress)

emphasized its connection to the study of Scripture. Like Ambrose, Gregory found the truest meaning embedded allegorically in the biblical texts, and through grace the student reaches that level of understanding of truth and through that truth finds God. When the mind is raised to God, the spirit follows. Truly pastoral, Gregory notes that any Christian can achieve this, to be a "contemplative in action," although it is easier for the monk.

Known as Pseudo-Dionysius, the Greek-speaking sixth-century author of *Divine Names* and *Celestial Hierarchy* provided a Neoplatonically inspired great chain of virtues—paralleled by the nine orders of angels—by which the

➤ PSEUDO-DIONYSIUS ON ASCENT THROUGH PRAYER TO DIVINE KNOWLEDGE, SIXTH CENTURY

“So let us stretch ourselves prayerfully upward to the more lofty elevation of the kindly Rays of God. Imagine a great shining chain hanging downward from the heights of heaven to the world below. We grab hold of it with one hand and then another, and we seem to be pulling it down toward us. Actually, it is already there on the heights and down below and instead of pulling it to us we are being lifted upward to that brilliance above, to the dazzling light of those beams. . . .

That is why we must begin with a prayer before everything we do, but especially when we are about to talk of God. We will not pull down to ourselves that power which is both everywhere and yet nowhere, but by divine reminders and invocations we may commend ourselves to and be joined to it.”

Source

Pseudo-Dionysius, “The Divine Names,” in *Pseudo-Dionysius: The Complete Works*, translated by Colm Luibheid (New York: Paulist Press, 1987), 68.

Christian is led back to God. Becoming God by adoption proceeds from purgation to ignorance, to illumination by wisdom, and finally to perfection by deification. This author does not speak of his own experience but instead provides a guide for the contemplative. In the ninth century, the Irish monk John Eriugena translated the Greek work at the French king’s request. His commentaries on St. John and the *Celestial Hierarchies* gave him a forum for expressing his understanding of deifying contemplation. Influenced also by Ambrose and Augustine, he developed the theme of the spiritual life founded on meditative prayer, the prayerful reading of Scripture, and participation in the Church’s liturgy.

Islamic Mysticism

Islamic mysticism, or Sufism as the Arabic word *tasawwuf* is often translated, is a spiritual trend developed in the heart of Islam from the very first centuries and widely spread in Islamic societies at every level. It is an articulate initiatory institution neither merely religious nor merely philosophical that includes ritual, doctrinal, and social aspects. Mystics themselves distinguish the religious exoteric sciences (*ilm al-zahir*, i.e., scholastic theology, religious jurisprudence) from the science of interior (*ilm al-batin*, i.e., mysticism itself). What discriminates Sufism from discursive knowledge and philosophy are both a set of ritual practices, such as voluntary fasts, litanies, retreats, and seclusions, and the conviction, so frequently maintained, that speculative and rational learning is not sufficient: to quote a mystic’s utterance, reason allows man to explore the created world, but if it turns to the Creator, it will be liquefied.

From the very beginning, the mystics’ experience is shaped as a spiritual path (*suluk*). The mystic (*Sufi*) is depicted as a wayfarer crossing stages and permanent spiritual stations (*makamat*) that he can achieve through his personal effort. However, these spiritual states (*ahwal*) are transitory divine gifts. The engagement in the Sufi life is ruled also from the social point of view. It is believed that the possibility of such a wayfarer reaching the spiritual goal without help is rare. Any aspirant to God (*murid*) must be the disciple of a master (*shaykh*) who receives his oath of allegiance by the hand clasp (*abd*), teaches him a secret litany (*wird*), casts on him the spiritual blessing (*baraka*) he inherited from a chain of masters linked to Prophet Muhammad, and leads him to get rid of his lower passions in order to ascend through the spiritual way. The final aim is to purify the self: once they

removed the veils of ignorance that separate man from God, the Sufi will annihilate his individualistic identity, will be filled by the divine attributes, and will permanently remain in God so that God himself becomes the ear he hears by, the eye he sees by, the tongue he speaks by.

These defined features are common to the whole movement. Nevertheless, one can find a progressive development in Sufism. Masters belonging to lands and centuries far from each other will contribute progressively to clarify concepts that were present from the beginning, even if in a less evident way. The concept of Sufism itself appeared as such only at a later time, and the word from which it derives, *Sufi*, was used for the first time about a century after the rise of Islam. Furthermore, the collective name that means the whole class of the Sufis (*sufiyya*) is not found before 815–816.

What happened in the meantime? Spiritual trends flowed free. To understand the origins of Islamic mysticism, one has to pay attention to a famous statement of the Khorasanian Sufi named Fushanji (d. 959) complaining about the bad spiritual situation of his age: “Today Sufism is a name without a reality, but it used to be a reality without a name.” Indeed, among the party of the primitive Sufis, one can find the names of Ali (d. 661), the fourth caliph and the transmitter of the esoteric knowledge, and the People of the Bench (*ahl al-suffa*), a group of poor Muslims who lived next to the first mosque in Medina, devoted to day fasting and nightly devotions. Subsequently, those who pursued the spiritual path were generically known as ascetics (*zuhhad*) without being distinguished from the ordinary believers by any exterior sign. Only as early as the middle of the ninth century, Sufis were known to be a peculiar group marked by more or less standardized spiritual practices and mystical doctrines.

When Baghdad was founded (762–763) and became the capital of the Islamic empire, it drew, besides commerce, also learned men of many kind. Sufi masters collected small circles of followers, although without creating real initiatory orders for the moment. Nevertheless, their teachings were of such significance that they molded the later development, thus making the school of Baghdad renowned as classical Sufism. The enlargement of the audience favored

> WERE THERE SUFIS BEFORE MUHAMMAD? THE MANY POSSIBLE ORIGINS OF THE WORD “SUFİ”

The etymological origin for the Arabic word “Sufi” has been debated throughout the centuries. Different interpretations have been set by both Islamic mystics and Western scholars, each of them enlightening one or more features of the spiritual movement itself. The hypothesis most accepted by both sides is that the word comes from the Arabic *suf*, meaning “wool,” a raw, rough, and poor material that ascetics used to wear to demonstrate their choice of forgoing worldly pleasures and devoting themselves to poverty and renunciation, looking for the delight in the thereafter. A further historical hypothesis—although philologically impossible—deals with the *ahl al-suffa* (people of the bench), the group among the first Muslim devotees living in the space between the first mosque in Medina and Prophet Muhammad’s place. In others’ opinion, the word would result either from *safa* (purity), as mystics purify their heart for the sake of God, or from *saff* (row), because out of their devotion they would hold the first place in front of God. Hypotheses of derivations from other words are seldom suggested and sometimes definitively rejected, among them the Greek *sophos* (wise), which would give Sufism an extra Islamic origin by linking it up with the Hellenistic philosophy, and the Arabic *sufana*, a plant on which ascetics would have fed at the beginning. Noteworthy in the end is the connection with the name of Gawth, son of Murra, called Sufa, who lived in total devotion five generations before the birth of Muhammad. This hypothesis would date the origin of the word before the revelation of Islam itself, thus linking it to a priestly tradition that initiated into the pilgrimage to the Kaaba.

—Marco Aurelio Golfetto

the increase of speculative doctrines, and world denial, although pursued, was now openly perceived as an introductory stage for acquiring the science of divine things. Besides classifying the spiritual experiences they enjoyed, the masters of this age went deep into the description of the higher steps of self-realization. Junayd (d. 910) is one of the most noteworthy personalities of this school. As a champion of inner sobriety, seriousness, and equilibrium, he probed the doctrine of

the Unity of God (*tauhid*) from the spiritual point of view, accordingly describing the initiatory path as a being's permanent striving to return to his original and pure state in God, as before the creation itself.

A completely different attitude from Junayd is found in further masters, whose engagement into the path is marked by divine attraction and love. Among them was Bistami (d. 874), well known for his ecstatic utterances, who is considered to represent the trend of intoxicated mystics. Despite his fame, he was possibly one of the inspirers of the important current of those who draw blame upon themselves (*malamatiyya*), which developed in Khorasan during the ninth century. Brotherly opposed to the Iraqi school, *malamatiyya* loved to hide their spiritual highness. Outwardly behaving in an apparently ordinary or even reprehensive way, they could devote themselves to the exclusive worship of God by giving permanent thanks for his grace he bestowed and jealously guarding the secrets and mysteries he revealed to their souls. On the contrary, the tendency to divulge the inner secrets was carried to an utmost extent by Hallaj (d. 922), the "martyr of divine love," who paid with his life for his utterances about the extreme mystical union of the Sufi with God, famous is his phrase "I am the absolute Truth" (i.e., God). His doctrines and beautiful poems produced two opposite effects: they enlivened the experience of later generations of Sufis and broke the balance between mysticism and secular religion.

The crisis that exploded because of Hallaj's scandal lasted for almost two centuries. During

this time, even more than in earlier and later ages, mystics were charged with extravagancy, boasting, and even heresy. Consequently, it was necessary to arrange an apologetic action that on the one hand defended the honor of the institution and on the other hand condemned heterodox doctrines and attitudes. As early as the middle of the tenth century, numerous handbooks were written to explain the real nature of Sufism. Authors such as Sarraj (d. 988), Kalabadhi (d. 995), Qushayri (d. 1072), and others not less important did their best to prove the accordance of Sufism with the Quran, the prophetic tradition (*sunna*), and the orthodox theology; to clarify the masters' deeds, teachings, and their use of technical lexicon; to justify their ecstatic utterances and the possibility of performing miracles (*karamat*); and to blame practical and philosophical mistakes of the individuals. However, it was only the unique personality of Ghazali (d. 1111) that could definitively accomplish the work of reconciling the spiritual path with the exoteric law and establishment.

Science and Technology

In this era, technology and science were two separate domains that only occasionally affected one another. Technology was developed by practical artisans and craftsmen who were less interested in scientific theory and mostly concerned with practical and, occasionally, aesthetic issues.

Technology

The period 300–1000 CE is often thought of as being technologically stagnant in which very little change occurred. This is a misconception; in many ways this period was technologically innovative.

The most important technology of the era was that involved with agriculture, since all sedentary economies, in which the great majority of the world's peoples lived, were overwhelmingly agricultural. During this era, substantial and important cumulative change, though at a gradual and incremental pace, occurred in agricultural technology, particularly in the development and diffusion of crops. These new crops, chiefly diffusing from Mesoamerica and South and Southeast Asia, produced agricultural revolutions in southeastern and southwestern North America, the Muslim world, and Africa south of the Sahara. In previous centuries, maize, beans, and squash had been developed by selective breeding to mature in progressively shorter growing seasons. In this period the farming peoples of the North American Southeast and Southwest adopted these originally tropical plants to supplement their plantings of sunflowers and amaranth. In the Muslim world, the adoption of water-loving hot weather summer crops—rice, bananas, sugarcane, taro, citrus fruits, cotton, etc.—from India and Southeast Asia to supplement the wheat, olives, and other Mediterranean winter crops resulted in a doubling of agricultural production in areas where intensive irrigation was possible. In China, the diffusion of cotton, sugarcane, and taro enriched the economy of southern China and the Yangzi Valley.

In Africa south of the Sahara, the introduction of bananas, sugarcane, taro, and rice resulted in significant population increases as well as social and political changes by 1000 CE.

China led the world in other changes in agricultural technology, particularly in intensive farming. Animals were increasingly confined to enclosures, manuring and fertilization were carefully practiced, new methods of water-conserving cultivation were developed, and elaborate systems of crop rotation and diversification were increasingly used. These Chinese farming techniques, which were also adopted in Korea, Japan, and Vietnam, required intensive use of human labor. The invention of seed drills and horizontal windmills and waterwheels during

this era may have reduced the labor burden somewhat. In the middle of this era, the Chinese developed improved harnessing systems, including the horse collar that made it possible to use horses to pull heavy loads. When the horse collar spread east across the Eurasian landmass, the Slavic peoples and then the West Europeans began to use horses to pull moldboard plows in the heavy North European forest soils.

The most important agricultural innovation in the Muslim Agricultural Revolution, after the adoption of South and Southeast Asian crops, was the improved irrigation systems, which these new crops demanded. In addition, Muslims in Afghanistan developed vertical waterwheels and windmills.

Any survey of medieval agricultural technology across the globe must include the ingenious system of raised beds by which the natives of Tiwanaku moderated the microclimates of their fields and the terrace irrigation of the Andean and northern Philippine cultivators.

Changes in transportation technology accompanied agricultural change. One of the most impressive of these transportation developments was the heavy investment by the Sui and Tang dynasties in canals, canal locks, and bridges. It was in this era during the Sui dynasty that the first Grand Canal was begun. Other innovations in overland transportation technology involved the increased use of the camel rather than the oxcart. The extensive use of camels began as early as the first century CE and by 300 had expanded to become a hemisphere-wide phenomenon. Camels, which could carry loads of several hundred pounds over roadless terrain, not only made redundant elaborate road systems such as the Romans had constructed but also made possible much more robust overland transcontinental trading systems such as the trans-Saharan routes or the Silk Roads. These overland routes were always supplemented by river transportation where this was possible or coastal sea transportation.

In sea transportation, the monsoonal pattern of Indian Ocean trade, discovered about the beginning of the first millennium CE, became extensively used as Indian Ocean trade burgeoned after 650 CE. Ships began to sail far out to sea, using the lateen sail to tack into the wind. This technique, perhaps first developed by the Polynesians and adopted from them by the Indonesians, began to be used by the Indian Ocean Arab

seafarers in this era. It spread to the Italian merchants by or after the end of this period (1000 CE).

Chinese innovations in sea transportation included the sternpost rudder and, toward the end of this period, the magnetic compass. The Polynesians developed highly sophisticated navigational techniques, including the double-hulled and outrigger canoes as well as sailing in the wind techniques that enabled them to colonize most Pacific islands as well as visit

The Polynesians developed highly sophisticated navigational techniques, including the double-hulled and outrigger canoes as well as sailing in the wind techniques that enabled them to colonize most Pacific islands as well as visit South America by 1000 CE.

South America by 1000 CE. While the Polynesians were crossing the Pacific, the Vikings were crossing the Atlantic in their much less technologically developed open boats.

In the Americas, transportation was by seagoing boats or rafts or overland by human runners or carriers. In the Andes, llamas as pack animals supplemented these, and where there were rivers such as the Mississippi or Amazon, they were supplemented by dugout canoes.

The technology of war and war making was also very important in this era, as in others. This involved fortifications, weapons, projectile weapons, flamethrowers and firearms, bows and arrows, body armor and horses, and camels and elephants. There were few innovations regarding fortifications during this era; the basic technology of defensive walls before the advent of cannons had been worked out thousands of years earlier. Nevertheless, defensive walls, such as the Danewirke in Jutland and Offa's Dyke that protected Mercia from Welsh raids, were still being constructed. Walls usually protected cities, and various types of rock or projectile-throwing devices—trebuchets, onagers, and catapults—were employed to knock them down. One of the more effective weapons used to break a siege was "Greek fire," a kind of flamethrower used by the Byzantines to break the Arab sieges of Constantinople (674–678 and 717–718).

Handheld or thrown weapons changed little. Most of these were close combat weapons: a variety of spears, javelins, swords, battle-axes, and the like, with cutting edges of iron, steel, bronze, flint, or obsidian. Gone were the days when highly disciplined armed groups, such as those of the late-first-century BCE Greeks, charged the enemy with long pikes in phalanxes. Most of the innovations in handheld weapons were in projectile weapons: the use of compound bows and the elaboration of crossbows, which had been in use in China since the third century BCE. Although the Chinese had invented gunpowder, it was seldom used in combat until after this era.

Perhaps the most far-reaching military innovations involved horses and cavalry. In this aspect of military technology, the Chinese are credited with many of the innovations, such as the horseshoe and stirrups (which allowed the rider to exert more force in making spear thrusts). These innovations made their way west, to be adopted by the Muslim armies and then the Europeans. The stirrup together with the European invention of the saddle with pommel and cantle is often credited with causing a military and political revolution in western Europe. But these would have been unlikely without the simultaneous emergence of a war-horse large and powerful enough to charge with a heavily armored knight carrying a long metal-tipped lance. These horses were specially bred and fed a rich diet of alfalfa (or clover) and grain. The care and feeding of these horses became one of the chief concerns of feudal society.

The technology of making tools, weapons, ornaments, and utensils—materials technology—was important. Many agricultural and household tools were made of wood, but some were made of metal, glass, or ceramics. Most peoples made ceramics, but the best were the porcelain, made by the Chinese. All sedentary societies in the Eastern Hemisphere made, or at least used, iron. The Europeans and Muslims made chiefly wrought iron, the Chinese made chiefly cast iron, but the people of India were the most accomplished iron metallurgists and made superior wrought iron as well as steel. Metallurgists in Africa

south of the Sahara smelted iron but also worked in copper and copper alloys, such as brass. The best metallurgists in the Americas were in the Andes civilizations, where copper and copper alloys such as bronze and tumbago were produced. Metallurgy diffused slowly north from the Andes, through Central America to Mesoamerica. In Mesoamerica, metallurgy never occupied a very utilitarian niche because of the abundance of easily worked obsidian and flint.

Many of the early medieval innovations in industrial technology originated in China. Porcelain, paper, printing, gunpowder, the magnetic compass, the seed drill, the butterfly-winged horse hoe, the horizontal waterwheel and windmill, deep drilled wells, iron bridges, horseshoes, horse collars, and stirrups are some of the innovations in industrial technology attributed to the Chinese. The question emerges: Why was China a fount of innovation in the medieval period? Several explanations suggest themselves. China had the largest and most dense population of any society on earth, and moreover, that population at several times in the early medieval period probably had the highest material standard of living. During these periods, many people had living standards above the bare level of existence and were less resistant to the idea of innovation. Moreover, China was the most urbanized society and was less conservative than more rural societies.

Science

The advance in scientific knowledge and theory was much less dynamic during this era than technology. Indeed, in some respects, much of the scientific thought that had been developed during the classical eras of the Roman empire and the Han dynasty was lost with the collapse of these empires. Chinese science did recover during the Tang dynasty, but science in Europe did not revive until the fourteenth century. While science in Europe suffered, India and, coincidentally, the Maya in Mesoamerica led the world in mathematics and, to a lesser extent, astronomy. In the eighth century, the Chinese had recovered much of their leading role, especially in materials science (alchemy), but in the ninth century, the efforts of a group of brilliant Muslim alchemists laid the groundwork for modern chemistry.

The ninth through the twelfth centuries witnessed a great surge in scientific and general intellectual achievement in the Persian-speaking lands of Iran and central Asia. This upsurge, sometimes referred to as the Samanid Renaissance, found an echo in a parallel spike in scientific work in late Tang and early Song China. This renaissance was studded with a group of polymaths, renaissance men who made contributions in such diverse fields as theology, philosophy, medicine, mathematics, astronomy, optics, cartography, geography, history, prose literature, and poetry.

Four factors contributed to the surge in Chinese and Muslim scientific achievement in the later centuries of the first millennium CE: increased wealth, urbanization, intercontinental trade, and greater ease in communication due to the diffusion of papermaking and, in China, printing. To this list, one is tempted to add the establishment of institutions, such as Baghdad's House of Wisdom or China's Imperial Acad-

emy, which facilitated the transmission of knowledge. China's economic leadership during this period stimulated the scientific enterprise, but toward the end of this era, the Muslim world surpassed China in some scientific areas.

The Muslim world's principal advantage was its location. Situated in the midst of the major civilizations of the Eastern Hemisphere—China, India, the Greco-Roman civilization of the Mediterranean—and interacting with all of them, the Muslim world was, more than China, the Middle Kingdom, the Central Civilization. The Muslims were heir to the great scientific advances of the classical Hellenistic savants, they were privy to the mathematical and astronomical knowledge of India during the Gupta period, and they absorbed much of the technological innovations of the Chinese. Muslim thinkers made a synthesis of scientific ideas from all these sources and, in doing so, made new scientific breakthroughs.

The great mathematical and astronomical advances of the Maya derived from sources similar to those that fueled China's technological and scientific prowess. In its age of glory, Maya-land was a rich, densely populated area that supported many wealthy cities. The Maya apparently had a well-educated creative class of scribes whose endeavors were facilitated by a writing system using bark paper. It is unknown how much the Maya benefited from contacts with the non-Mayan parts of the Mesoamerican ecumene, or from contacts with areas beyond Mesoamerica.

Science in this age was heavily influenced by and mixed with magic, sorcery, occult ideas, and superstition. Astrology (the idea that human affairs were controlled by stars, planets, and other celestial bodies) was a dominant belief in every civilization, and astrologers were revered. Magicians and sorcerers did not usually enjoy the high status of astrologers, but they were feared, and their services were avidly sought. Most people gave credence to occult or esoteric sciences such as the Jewish cabalists, the Shia esoterics, the Hindu and Buddhist Tantrics, or the Chinese Daoists. And even those thinkers who did not traffic in these pseudosciences often tried to keep their discoveries hermetic (hidden), available to only a select group. Thus, the great eighth-century Baghdadi alchemist Abu Musa al-Jabir (known in Europe as Geber) reported his discoveries in code that was intelligible to the elect but to most people seemed to be gibberish.

Medicine, alchemy, mathematics, astronomy, optics, geography, and history were the disciplines in which the most important advances were made during this era.

In medicine, the major civilizations of the Eastern Hemisphere relied principally on three traditions at the outset of this era: the Hellenistic-Roman, the major spokesmen of which were Hippocrates and Galen; the Chinese, which was heavily invested in acupuncture and Daoist lore; and Ayurveda, whose worldview was shaped by Indian

Science in this age was heavily influenced by and mixed with magic, sorcery, occult ideas, and superstition. Astrology (the idea that human affairs were controlled by stars, planets, and other celestial bodies) was a dominant belief in every civilization, and astrologers were revered.

tradition as well as by Buddhism. Ayurveda relied greatly on herbal medicines as well as teaching moderation in diet, food, sex, and the like, but it also employed plastic surgery as well as surgery to remove cataracts and for amputations, closing wounds, and caesarian births. Ayurveda became part of the intellectual portfolio carried by Buddhist missionaries to China, where it heavily modified traditional Chinese medicine.

Meanwhile, in the Roman empire, medical doctrine, which had been elaborated by Hippocrates (traditional dates 460–270 BCE) and Galen (129–200 CE), was being supplanted by Christian teaching. In the fifth and sixth centuries, heretical Christian doctors first at Edessa and later at the Persian institution at Gondeshapur were teaching this traditional Hellenistic medical lore. When the Muslims conquered Persia and most of the Asian provinces of the Roman empire, the Muslim authorities favored the doctors at Gondeshapur and had them translate the works of Hippocrates and Galen into Arabic.

The Muslims also studied the chief Indian works on Ayurveda, and from their understanding of Hellenistic medicine and Ayurveda they developed Arabic medicine. Arabic medicine, learned through the *Comprehensive Book of Medicine* of Mohammad Rhazi (865–925), known in the West as Rhazes, and the *Canon of Medicine* by Ibn Sina (980–1037), known in the West as Avicenna, was fundamental to medical science in Christian Latin Europe until the seventeenth century.

The modern science of chemistry grew out of the ancient alchemy. Alchemy was practiced in China, India, and the Muslim world, from

which it spread to Europe toward the end of this era. In ancient China, alchemy was an outgrowth of the search, by Daoist adepts, for an elixir of immortality. In their experiments, the Daoist alchemists developed a vast pharmacopoeia, a great list of drugs reputed to be efficacious in treating many diseases. The Daoist alchemists were also intent on transforming base metals into gold. Daoist alchemists are credited with discovering the secret of making gunpowder, one of the most consequential inventions of early medieval China. Daoist

In ancient China, alchemy was an outgrowth of the search, by Daoist adepts, for an elixir of immortality. In their experiments, the Daoist alchemists developed a vast pharmacopoeia, a great list of drugs reputed to be efficacious in treating many diseases.

adepts cloaked their craft in mystery, teaching that it had a spiritual dimension that demanded physical and mental discipline. Yoga became an integral part of their discipline.

In India, alchemy with its magico-spiritual dimension was largely influenced by Chinese Daoism beginning in perhaps 300 CE. Indian methods of smelting and isolating metals, such as zinc and mercury, became an integral part of alchemical lore. The Indians developed methods of distillation and the production of acids that the Muslims would later further develop.

Early medieval alchemists of the Muslim world were indebted both to Persian scholars, particularly at the Sassanian medical school at Gondeshapur, who had preserved classical Hellenistic as well as Persian alchemical lore, and to translations of Indian works, which in turn had been

influenced by Daoist practice. In the ninth century, alchemy as practiced at Baghdad and the Persian city of Rayy became the most advanced in the early medieval world. Al-Jabir was, in many respects, the star of medieval alchemy. For al-Jabir, experimentation was more important than any spiritual or magical dimension of the craft. For this reason, he is sometimes called the Father of Chemistry. Al-Jabir isolated and identified a number of metals, including arsenic, antimony, and bismuth, and produced several acids, including sulfuric, hydrochloric, and others. One of his discoveries, the distillation of alcohol, was to have serious social consequences when the Europeans learned of it in the twelfth century.

In the early medieval age, mathematics and astronomy developed in tandem. The most advanced mathematics and astronomy for most of this period were that of India and, in some respects, that of the Maya. The Maya and the mathematicians of India both discovered the concept of zero at about the same time. The Maya predicted solar and lunar eclipses and calculated the length of the solar year at nearly the same value that modern astronomers assign it. Unfortunately, we do not know the names of any Mayan mathematicians or astronomers.

The period 400–1200 has been called the golden age of Indian mathematics. During this period, there were many great Indian mathematicians, a number of whom were followers of the Jain religion. The most influential, because their works were later translated into Arabic and so influenced Muslim and through them European mathematicians, were Aryabhata (476–550 CE) and Bhramagupta (seventh century). The Indian mathematicians not only developed the concept of zero as a number and a place holder and were the first to use so-called “Arabic” numbers but also devised the rules for trigonometry and much of algebra and made a beginning of calculus.

Indian mathematics spread north to China and west to the Muslim caliphate. During the Northern and Southern dynasties and the Sui and Tang dynasties, Indian mathematicians were often employed by the imperial calendar bureaus, but the Chinese preferred their own mathematical system and rejected much of the Indian mathematicians’ advice. Chinese mathematics and astronomy was dominated by the outstanding achievement of Zu Chongzhi (429–500) who, in devising the Daming calendar, calculated the length of the solar year to within 54 seconds of modern astronomers. Two and a half centuries later (727), Yi Xing, in an improvement on Zu Chongzhi’s work, introduced the Dayan calendar by which one could calculate phases of the moon, equinoxes, and many other celestial events.

Unlike the Chinese, Muslim savants eagerly embraced Indian mathematics. Muslim mathematicians built on the Indian teachings, and mathematics became one of the jewels in the medieval Muslim intellectual crown. An influential Muslim mathematician (as well as astronomer and geographer) was al-Khwarizmi (780–850), whose work introduced Muslim mathematics to Christian Europe and from whom the algorithm gets its name.

Chinese and Muslim cartographers developed mapmaking to its medieval apogee. Both devised systems of latitude and longitude. Muslim cartographers and astronomers also developed spherical trigonometry

to aid them in plotting distances. The Persian polymath Al-Biruni was a leading Muslim scholar in this field.

As this essay attempts to show, the early medieval age was by no means the sterile technological and scientific wasteland that some scholars, impressed with the European Dark Ages and not

aware of scientific and technological developments in non-Western civilizations, sometimes consider it. Technological and scientific change was uneven and sporadic, sometimes halting, but the technological and scientific landscape in 1000 was much different than it had been in 300 CE.

—Wilfred J. Bisson

■ Introduction: Agricultural Technology

Agriculture was the economic basis of almost all sedentary societies in the period 300–1000 CE. Because the great majority of the earth's people lived in sedentary agricultural societies, agriculture involved the most fundamental, most important, and widely understood technology of the age. This technology shaped most of the world's cultures and was woven into the folkways of the globe's rural majority.

Agricultural technology dictated the people's response and adaptation to the environment. The climate, length of the growing season, amount of rainfall or availability of water, and type and nature of soils as well as the nature of the crops and domesticated animals were among the factors in this adaptation.

The most widespread type of technology affecting agriculture was that of hydrological management: the techniques of controlling the water supply by irrigation to prevent desiccation in times of drought and drainage channels to remove excess water in times of floods. This technology was nearly as old as sedentary agriculture and was practiced in one form or another by most agricultural societies. The least labor-intensive irrigation occurred on seasonally flooded river valleys, such as in Egypt, but many irrigation systems required elaborate engineering and great amounts of labor in their construction and maintenance. These systems included dams and reservoirs (tanks) to impound water from the rainy season, as in India, Southeast Asia, South Arabia, and the North American Southwest; elaborate systems of laboriously dug irrigation canals in Peru, China, Mesopotamia, and many other regions; under-

ground channels dug through rocks to conduct water from aquifers to irrigable fields in Persia, central Asia, North Africa, and elsewhere; and hand-dug wells in most arid regions. All of these systems depended on a gravity flow of water, but in many regions, such as in Nubia and Egypt, mechanical devices were used to lift the water. The Chinese used chain pumps, powered by humans, as well as other devices. In many regions, animal-powered water wheels, which lifted water in a series of clay pots, were used. In mountainous areas such as the Philippines, the Andes, and elsewhere, terraces were built to conserve moisture or to create level areas to grow rice and other crops. In arid regions such as northwestern China, farmers conserved moisture by planting their crops in furrows between ridges or in pits dug into the soil.

An ingenious system of water management, designed not so much to irrigate crops as to control the microclimate, was that of Tiwanaku (in current-day western Bolivia). In the wetlands adjacent to Lake Titicaca, the Tiwanaku constructed raised beds surrounded by deep-water channels. The Tiwanaku raised abundant crops, mainly potatoes, on these raised beds despite the killing frosts that often visited this area, which has an altitude of 14,000 feet. The water in the water channels was heated by solar radiation during the day; at night it released heat, protecting the crops on the raised beds from frost.

In most segments of the Afro-Eurasian ecumene farmers raised crops and tended animals. Horses, until the invention of the horse collar (probably in China or central Asia about 500 CE)

were used mainly for war and as pack animals. Increasingly after improved methods of harnessing them for load pulling had diffused through the ecumene, they were used to pull plows and heavy loads. But the majority of animals used to pull plows were cattle or the related water buffalo. Europe, the Muslim world, India, and Southeast Asia employed a mixed livestock- and crop-raising strategy that required the allocation of arable land for pasture and grazing. In China, Japan, and Korea most of the few farm animals were kept in pens or stalls, and fodder was brought to these animals so that almost all arable land could be continuously cropped.

Wheat, barley, millet, and rice in the Eastern Hemisphere and maize in the Western Hemisphere were the principal grains forming the basis of agricultural life. Iron hoes, sickles, and animal-drawn plows were the common tools. In most of the world, planting the seed was a laborious task done by hand and sometimes with digging sticks, but by 500 CE the Chinese had developed a mechanical seed drill to expedite the task.

Wet-rice farming was the most widespread as well as the most productive crop in this time period. Rice was the major crop in the southern two-thirds of China and was becoming a prestige crop in Korea and Japan. In most of Southeast Asia as well as much of India, rice was intensively cultivated. During this era, rice cultivation diffused through the Muslim world and to Spain and Italy. Indian Ocean traders established rice farming on the east coast of Africa, while Malagasy colonists brought it to Madagascar. Rice was a prestige grain consumed by elites, but its production was one of the most labor-intensive types of farming. In East Asia as well as in India, rice seedlings were carefully started in special beds and about 40 days later, when the seedlings were a few inches tall, laboriously hand transplanted in the flooded mud of rice paddies. Rice production, which required arduous and constant manual labor, involved constructing level rice paddies with dikes to hold the water, repeatedly plowing the soil to create a mud slurry, flooding and draining the paddies several times a year, transplanting the young seedlings, carefully weeding the growing rice crop, harvesting the stalks with hand sickles, and threshing, milling, and polishing the grain.

China led the world in agricultural technology during this era. Chinese farmers invested a great amount of labor on small units of land, but their agricultural productivity per laborer as well as per unit of land was the highest of any large society. The Chinese accomplished this by growing a wide variety of crops carefully selected to match the soil, climate, and growing season. They alternated nitrogen-demanding crops, such as wheat and rice, with nitrogen-fixing plants, such as beans, particularly soybeans. Their methods of crop rotation made it possible to harvest multiple crops annually, year in and year out. Chinese farmers had no need to leave land fallow so that it could recover its fertility, nor were they obliged to set aside areas to pasture animals. Since China's cultivated plants, particularly soybeans, provided all essential nutritional requirements, animal protein was a luxury.

During this period, the Muslim world experienced what has been called an agricultural revolution. The basically Mediterranean-style agriculture that had prevailed in the areas conquered by the Muslims were made much more productive by the introduction of crops from India that were grown in heavily irrigated fields in the dry Mediterranean summer. This addition of a summer crop to the cool, wet winter crops, particularly wheat, traditional in regions with Mediterranean climates, made it possible to nearly double agricultural production.

The emergence of the Islamic empire and the great increase of Indian Ocean trade resulted in accelerated diffusion of many South and Southeast Asian crops to West Asia, the Mediterranean region, Europe, and Africa south of the Sahara during this era. Crops such as sugarcane, cotton, rice, bananas, lemons and other citrus fruits, taro, and coconuts, as well as Asian chickens, were thus spread. As these crops, particularly bananas, spread across the continent from the east coast of Africa, they wrought great changes in demography as well as agricultural technology. In the African Great Lakes region and the equatorial rain forest as well as in forested West Africa, the addition of these crops to the traditional yam- and groundnut-based African forest agriculture produced food surpluses that led to increased population growth, which in turn fostered the formation of kingdoms and

states. The basic tool used by most African farmers was the heavy short-handled iron hoe, though in the Ethiopian highlands wooden plows pulled by oxen were common.

In the Americas, where it has been estimated that 60 percent of the food crops known to modern humanity were domesticated yet agricultural tools were simple, the technology of irrigation, plant selection, and seedbed preparation was very sophisticated. The hand tools used (Native Americans had no plows because they had no domestic animals capable of pulling a plow) were usually made of wood but sometimes of antlers, bone, or conch shells. In the North American Eastern Woodlands, elk and moose antlers served as shovels, but elsewhere the wooden digging stick was the principal implement. In the Andes the foot plow, a wooden implement with which the farmer could use his foot to add the force of his weight for digging, was ubiquitous.

Irrigation systems in the Americas included catchment dams, contour-built irrigation canals, and raised beds as well as ridge and furrow fields to preserve moisture. Native Americans planted many crops, but the so-called three sisters—maize, beans, and squash—provided a balanced nutritional regime. This was very important for economies in which animal protein was scarce. The three sisters were domesticated in tropical Mexico where the growing season is more than 100 days, but by careful plant selection over many generations, North American farmers were able by 1000 CE to produce varieties of maize, beans, and squash that would reach maturity in 60 days or less. In 300 CE growing any of these crops north of Mexico was very difficult, but by 1000 they were being grown as far north as the Great Lakes and in the St. Lawrence Valley.

In Polynesia, farmers were using sophisticated strategies for producing crops, particularly taro and sweet potatoes. Complex irrigation systems watered taro, and pit cultivation fostered microclimates in which plants could be cultivated beyond the range otherwise possible.

Although rural people are of necessity very conservative, and changes take root among them slowly, a view of the long duration of this era's seven centuries shows significant innovations in agricultural technology.

Agricultural Innovations in East, Central, and Southern Africa

Between 300 and 1000 CE Bantu-speaking peoples moved into the diverse ecological areas of East, central, and southern Africa. They adapted agricultural technologies from the people already living in the region and invented new ones. They were able to settle and create food-producing niches by raising cattle in the drier regions where there were no tsetse flies and engaging in agriculture in the areas of better rainfall where tsetse flies could breed. The gatherers and hunters continued their form of food production and offered alternative sources of food in areas where agriculture or livestock raising was more precarious.

By 500 CE the gathering and hunting peoples in southern Africa had added livestock raising to their food-producing strategies. Bantu-speaking cattle herders supplemented their food production by learning the techniques for gathering of plants, small animals, and insects of the area and how best to hunt the larger animals that roamed southern Africa. The integration of these various technologies for food production was probably the result of trade between the gathering and hunting peoples who could trade animal hides and ostrich eggshells for Bantu-manufactured goods such as iron pots and tools, baskets, and woodcarvings. By relying on more than one food-producing technology these peoples ensured survival in times of crises.

The click sounds, a trademark of Khoisan languages, are found in all the Bantu languages of southern Africa today. Bantu adoption of the click sound is linguistic evidence of the contin-

ued close contact over a long historical period among the gathering and hunting and the Bantu-speaking peoples of southern Africa.

The successful cattle keeping/gathering and hunting strategies also transformed the agricultural peoples of southern Africa. As soon as they began raising cattle, farmers moved into the drier savanna areas, expanding the Bantu-speaking populations and settling new lands.

In east-central Africa by 300 CE, food-producing communities had settled for the first time. The earliest of such communities were Bantu-speaking peoples coming from East Africa, bringing cattle into the drier, open savanna areas of east-central, central, and southern Zambia. Their expansion caused the eventual assimilation of the former Khoisan-speaking people of those areas into their societies. In land with good rainfall they grew grain crops. The Batwa fishing and gathering and hunting peoples persisted as culturally distinct in the swamps and wetlands around Lake Bangweulu.

Beginning around 600 CE, another group of Bantu-speaking peoples, the Sabi, moved from the Congo south into east-central Africa, where they adopted the agricultural techniques of the earlier peoples. They also added a technological innovation of their own in the form of slash and burn agriculture known as *citemene*. The land was not very fertile, so people began burning the trees on the savannas to prepare the soil for agricultural production. The ash from these burned trees provided the soil with essential nutrients. Increasing fertility allowed the Sabi to populate a region of marginal fertility. In the drier sections of southern Zambia the Botatwe absorbed the former cattle-herding peoples and began raising livestock themselves. They also continued their own type of slash-burn agriculture (*citemene*) in the wetter areas that were possibly infested with the tsetse fly.

In the rain forests of the Congo Basin of central Africa, Bantu-speaking peoples had cultivated yams since 3000 BCE, but around 600 CE bananas, an Indonesian crop, were introduced. Banana crops produced ten times more food than yams and were even better suited for the evergreen rain forests of central Africa. Also, banana cultivation was less labor intensive, which led to higher population densities among the Bantu-

➤ HUNTING AND GATHERING'S ALLURE

Do gathering and hunting peoples joyously embrace agriculture or pastoralism once established in an area? Most historians assume so. Yet the history of East, central, and southern Africa demonstrates that most gatherers and hunters in this region continued their way of food production well into the twentieth century. From 300 to 1000 CE agriculture was established and the newly settled communities were growing, yet the gathering and hunting peoples continued their own forms of food production and offered alternative sources of nourishment in areas where agriculture or livestock raising was more precarious. Hunters also played a role in the international trade since they hunted elephants for the ivory trade, which even 1,000 years ago was thriving.

—Christine Ahmed-Saidi

speaking farmers. In central Africa there are more than 120 different varieties of bananas, compared to only 12 types in Asia. Banana production allowed the agriculturalists to move into areas that had not been suitable for yam cultivation.

During the seventh century CE around Mount Kenya in East Africa the Thagiicu were still growing African yams in the damper higher regions but were also growing bananas, Southeast Asian yams, arrowroot, and later taro and sugarcane. In the drier lower lands the Chagga grew sorghum and pearl millet. These differing crops in a relatively small area allowed the development of intricate trading networks, which would eventually result in small states.

By 700 CE in the Western Rift to Lake Nyanza, the population of Bantu peoples had grown considerably. The need to place more land into agricultural production of bananas led to deforestation. Areas that were once thick forests by 1000 CE were becoming open grassland savannas. While deforestation seems like a disaster, the net effect of deforestation for the Lake Bantus was that it made the land excellent for livestock raising by removing the habitat of the tsetse fly. Soon communities such as the Batutsi began to depend primarily on cattle raising and were able to expand and later play a major role in the

development of the region. These cattle herders in turn helped the farmers. Fallow land could be used for grazing cattle, while the droppings of the cattle would help to fertilize the land and decrease the fallow time. The success of the blending of agricultural and livestock technologies resulted in larger population growth.

The Bantu adapted food-producing techniques from the peoples they encountered and innovated new methods. Their agricultural success laid the basis for several centralized states in the future but also allowed people in less fertile areas to continue to live and maintain their own decentralized communities. Gathering and hunting peoples, in some cases, were integrated into the agricultural societies, but many maintained their independence in part due to their ability to produce ivory and other items for the developing Indian Ocean trade.

Early Medieval Muslim Agricultural Innovations

Historians speak of an Islamic Agricultural Revolution, an Islamic agricultural golden age that lasted about four centuries (700–1100 CE). During this time many new crops were added to the Islamic agricultural portfolio, massive investments were made in irrigation, and innovations in agricultural practices and technology developed. Agricultural output expanded, supporting an increasing population. Old cities grew, and new cities emerged as commerce burgeoned.

The new crops, such as oranges and other citrus fruits, cotton, sugarcane, rice, bananas,

coconuts, taro, and mangos were mainly from Asia. Most of them, except for the citrus fruits, were from India, grown there in the hot summer when the monsoon rains lashed the land. The Muslims in the Mediterranean region and West Asia successfully adopted these Indian crops, but to do so they were forced to make large investments, especially in irrigation and hydrological management.

The Mediterranean climatic regime of the early medieval Islamic heartland favored the growth of wheat and other crops in the cool winter season, when most of the rain fell. But rice, sugarcane, cotton, and the other Indian crops grew best in the hot summer and demanded more water than the scant rains of the Mediterranean summer afforded. That the Muslims successfully cultivated the water-loving hot-weather crops is a testament to their technological development. By successfully growing these new crops, farmers in Muslim lands were able to add a summer growing season to their traditional winter growing season and, in the process, nearly double their production.

The Muslims inherited irrigation systems in most of the lands they conquered, but irrigation systems require constant attention and repair. Canals must be kept unclogged, wells cleaned out, and leaks in dams plugged. In many areas, because of war and social upheaval, these systems had often fallen into disrepair. But with the imposition of strong government, the Muslim conquerors mobilized the necessary labor not only to repair the existing irrigation systems but also to extend them and to construct new irrigation systems in new areas.

The most productive irrigated areas in the lands conquered by the Muslims were Egypt and Mesopotamia. It was Mesopotamia, or Iraq as it became known, in which the Muslims had their first great success. The Persians, from whom the Muslims conquered Iraq, had constructed irrigation systems around their capital, Ctesiphon. In this area, known as the Sawad, the Persians had maintained an intensive system of canals, which distributed water to a rich agricultural region, but to do this it was necessary to maintain close centralized control over the allocation of the water. The Muslim conquerors took over this Persian system, and the Iraqi Sawad became, for a

few centuries, the economic gem in the caliphate's crown. The Iraqi Sawad was, until the late tenth century CE, for the Abbasid caliphate what the Central Valley is to modern California: a veritable cornucopia. In the tenth century, geological changes, perhaps a slight rise in the height of the land in the Sawad, together with a deepening of the channel of the Diwalla River reduced the efficacy of the Iraqi irrigation canals.

Egypt was another economic prize for the caliphate. The annual Nile flood continued to fertilize and irrigate the Nile Valley, and the Muslims restored canals to the Fayum and some other regions. Egyptian agriculture was very productive because of the annual flood, but the agricultural year was confined to one growing season. In the dry season, with the river low, it was very difficult to irrigate the hot weather crops, such as sugarcane, that came from India. Only when the value of summer crops was sufficient to repay the heavy investment in labor required could hot-weather crops be grown. Water would be raised from the river by means of shadoofs, norias, Archimedes screws, and other devices, which required much human or animal labor.

In Iran and central Asia, the Muslims were heir to irrigation systems utilizing *qanats*, long underground tunnels dug by hand, sometimes through hard rock, to conduct water from an aquifer to the areas to be irrigated. Prior to the Muslim conquests, *qanats* had been largely confined to the Iranian plateau, but in the seventh and eighth centuries, the Muslims constructed *qanats* in Arabia, Syria, and Palestine as well as throughout North Africa, from Egypt to the Atlantic coast and from the Mediterranean to the Sahara Desert.

In addition to constructing *qanats*, Muslim agriculturalists tapped underground water by the extensive digging of wells. This was especially the case in Arabia and North Africa. On the route of the hajj, or annual pilgrimage to Mecca, pious wealthy Muslims made endowments for the digging and maintenance of wells, which were then also used for some irrigation. In the early Muslim centuries, many new wells were sunk throughout the Muslim world, and agriculture reached a relatively flourishing state.

Muslim farmers developed agriculture to a high degree in the early Muslim centuries with

the use of new crops, which allowed cropping in all seasons; the extensive use of irrigation; and heavy investments in labor, often slave labor. The ninth century was the golden age of agriculture in North Africa; in the tenth century, agriculture in Muslim Spain reached its apogee. Muslim agriculture basked in its high achievement for four centuries. Muslim scientists wrote treatises on agricultural techniques, the quality of soils, the choice and nurture of crops, and the like.

After the thirteenth century, a slow decline began to set in. A variety of factors may have been responsible for this: climatic and geological change, as in the Iraqi Sawad; destruction of cultivated lands by pastoral nomads, as in the North African Maghreb; and the breakdown of law and order and endemic warfare in much of the Muslim world.

Early Medieval Agricultural Technology in India and Southeast Asia

Developments in South and Southeast Asian agricultural technology made India and Southeast Asia leaders in agricultural productivity in the first millennium CE. Innovations included improved plant varieties and new types of irrigation works. These new technologies made agriculture more productive and supported growing populations throughout the region.

Early crops included millet, rice, sugarcane, yams, sago palm, bananas, and coconuts. Millet was primarily grown using slash and burn techniques especially in areas where irrigation was difficult or scarce. As wet-rice cultivation became more common, millet fell out of favor. Millet became associated with poverty and backwardness, while rice became highly valued as the chief staple throughout the region.

▶ EARLY MEDIEVAL AGRICULTURAL TECHNOLOGY IN INDIA AND SOUTHEAST ASIA— INTERNATIONAL TRADE ROUTES

Long-distance trade routes made it possible for new agricultural technologies to be adopted widely throughout the region. Trade also made it possible for new technologies and commodities to be introduced into the region from as far away as China, Arabia, and East Africa. Much of the trade was by sea except for the export and import of animals, which tended to be by land. The Chola kingdom of South India sent trade missions to China and imported high-quality horses from Arabia. Common commodities included rice, sugar, cardamom, cloves, indigo, opium, horses, monkeys, sandalwood, and teak.

—Eric Strahorn

Thousands of new strains of rice were developed by farmers who saved the seeds from especially productive plants. For example, the quick-ripening Champa varieties originated in what is now Vietnam around 100 CE. Intensive wet-rice production techniques, including multi-cropping and terracing, were developed in the highland areas of Southeast Asia to take advantage of these new varieties. Another important technique, the transplantation of rice plants, was first developed in southern China and was adopted throughout the area including northern and southern India, Vietnam, and the Malay Peninsula. The transplantation of rice plants involves the sprouting of seedlings in a seed bed separate from the main field. The seedlings are then transplanted into the flooded field by hand. The advantage of transplanting seedlings is that the main field can be used continuously. It also makes it possible to use the constantly flooded field as a fish pond. The presence of the fish improves the fertility of the soil, and the fish are an important source of protein for farmers. These new varieties and techniques spread throughout the region via the trade routes of Indian, Chinese, and Arab merchants and eventually transformed agriculture in India, Southeast Asia, and neighboring countries.

Rice cultivation began in river valleys and deltas, but in this period new irrigation technologies were developed that covered larger areas, al-

lowing for greater production. In the ninth century, the cooperative digging of irrigation channels made wet-rice agriculture possible in Java and Bali, while in Sumatra, deep-water and tidal irrigation technologies were developed in river basins. In the Chola kingdom in southern India, irrigation canals were built over several centuries on thousands of miles of the Cauvery River and its tributaries. These canals use an extensive system of anicut stone dams that could be nearly 1,000 feet (300 meters) long and 65 feet (20 meters) wide. An anicut dam is built in such a way that water flows over the dam and is diverted into irrigation canals. At its greatest extent, this series of dams provided irrigation water for more than 77 square miles (200 square kilometers). Throughout the region, smaller irrigation works were also constructed to store water for use in the dry season. Irrigation tanks could vary from small ponds 9 feet in diameter to substantial reservoirs covering several hectares.

There were also significant developments in other crops as well. Wheat is an important crop in the drier areas of North India but is a minor crop in South India and Southeast Asia. In North India, new varieties of wheat were developed that were better suited for local conditions by farmers who carefully selected seeds for the following year's crop. Irrigation works were built in places such as the Punjab in Pakistan, which has abundant rivers.

Sugarcane, cotton, and several spices are important cash crops in several areas throughout South and Southeast Asia. Technological advances with these crops were more in the area of harvesting and processing for market than in cultivation. Cotton from India was exported to the Middle East, while sugarcane tended to be consumed locally. Cloves, nutmeg, and mace were produced from trees that require very particular water and soil conditions. Farmers in Southeast Asia developed highly specialized methods to produce enough of these spices for export to India, Africa, Arabia, and Europe. For example, nutmeg trees require moist well-drained soil as well as partial shade. Clove trees also require partial shade, which is best provided by banana plants or albizias. Well-designed irrigation is necessary since waterlogging will kill both trees.

In the Gupta empire of northern India, new techniques in iron manufacture allowed for the

large-scale production of agricultural tools. An example of the quality of Gupta iron can be seen with the iron pillar located near the Qutab Minar in Delhi. This pillar is over 22 feet (7 meters) tall with a diameter varying from 14 to 17 inches (36–42 centimeters) and weighs more than 6 tons. The most distinguishing feature, however, is that the iron of the pillar has never corroded.

Knowledge of agricultural technology was transmitted in many different ways. In southern India, the poets of the Sangam period described different farming operations such as plowing, weeding, threshing, and the drawing of irrigation water from wells and lakes. Bullocks or steers were used to pull plows, thresh grain, and draw water from wells. In the Gupta empire, scholars produced numerous textbooks called *shastras* on a myriad of subjects including agriculture, horticulture, and animal husbandry. The *Brihatsambita* of Varahamihira discusses the proper ways to prepare seeds for planting as well as ways to treat diseases in plants, while the *Vai-syavarga* classifies different types of soils and advises as to which crops are best suited for each soil type. One of the most famous textbooks, the *Arthashastra* by Kautilya, is a treatise on political economy that advises the king on the management of irrigation; preparation of seeds for planting; proper care of cows, horses, and elephants; and the production of iron for tools and weapons. These texts were later brought to what is now Indonesia, especially Java, as Hinduism and Buddhism were increasingly adopted. In the Angkor region, temples served as storehouses of technical information on dam construction and various farming methods.

Agricultural Innovations in Europe

Developments in agricultural techniques and tools aided Europe's recovery from its fifth- and sixth-century population decline and climate cooling and enabled a northward expansion for crops that previously only thrived in the mild Mediterranean climate. Land, rarely vulnerable to raids and warfare, comprised wealth for almost everyone in the early Middle Ages. The majority of the population was involved in some aspect of agriculture, from the labor of tending the fields to tool production to the processing of food.

The estate (manor) system gradually replaced the Roman latifundium system in which large tracts of land were farmed by slaves. Changing climates and trade networks led to a decrease in population. It was no longer possible to run an economy on slave power, for such an economy depends on labor being extremely cheap. Early medieval rulers gave land (estates) to their followers in exchange for promises to serve them in war. An estate's tenants were given land to farm for themselves in exchange for farming the lord's land. Although most tenants (serfs) were not free people, they were able to inherit and will land. Estate complexes might also include fishponds, kitchen gardens for vegetables and herbs, beehives, and woodlands for material for building and fuel.

By the sixth century, a new and more effective kind of plow became popular, beginning in the north. The heavy plow offered a number of advantages over the previously common light plow. The heavy plow dug more deeply into the soil, turning it over more effectively, and fields only needed to be plowed once and not cross-plowed again afterward. Cross-plowing lends itself to square fields, while plowing only once led to the long, narrow fields. The heavy plow was more effective in turning over the rich alluvial lowland soils, which were increasingly farmed in the north. The plows were drawn by teams of oxen, and their efficiency improved as new types of harnesses developed that let the oxen stand one after another instead of side by side. With more land under cultivation and more oxen to feed, the scythe became a common instrument for cutting hay to feed them.

Beginning in the eighth century, three-crop rotation substantially increased agricultural

➤ WATER AND IRRIGATION

Too little water was as much a problem as too much: springs, aqueducts, and other purpose-built systems were tapped for seasonal irrigation in hot weather, especially for large vegetable gardens with water-hungry plants such as lettuce. Building an irrigation system required neighborhood collaboration, as the necessary ditches bringing water to a garden often crossed multiple property boundaries. Landowners whose property was crossed by these ditches made use of the irrigation system themselves in exchange for the use of their land. Smaller vegetable gardens were usually built near a convenient source of water such as a well.

—Shana Worthen

productivity. Two-crop rotation allows half of a manor's land to be cultivated at once; the other half lies fallow (unused) in order to recover from nutrient depletion. The following year, the fields will be reversed, with the fallow field plowed and planted. Fallow land could be productively used to graze cattle and sheep. In three-crop rotation, two different crops are grown each year, each in a third of the available land, with only a third left to rest.

A planting of winter crops, such as wheat or rye, would be followed by a planting of summer crops, such as peas, lentils, broad beans, oats, or barley. Crop diversity improved diets, reduced the chances of famine due to any one crop failing, and distributed the labor of plowing, planting, and harvesting throughout the year. The success of the system lay in choosing two different crops that require different nutrients and thus using the soil in complementary ways. Wheat and rye deplete the nitrogen content of soil, while beans convert nitrogen from the air into ammonia, which can be used as a source of nitrogen by other plants. Oats and barley had lower cultural status than wheat or rye and were often grown as animal fodder.

These agricultural developments enabled Europe's population to grow. The heavy plow, the three-crop rotation system, and the increased use of horses in farming were particularly advantageous in the heavier soil and colder climate of northern Europe, from the British Isles to what is

now Russia. The cooler temperatures that began with fifth-century glacial growth began to warm by the eighth century, creating a climate more conducive to farming. Thus, more and more land was cleared for cultivation in the north by draining swamps and cutting down woods. Dikes were built around low-lying Dutch bogs, holding back the ocean water in order to drain new land for agriculture.

Drainage also became more important. The cooler weather of the middle of the millennium led to much heavier rainfall and saturated soil, while land clearance led to erosion of topsoil. This caused rivers to silt up and increased the amount of marshy land, which required drainage to be reclaimed as farmland. Not all marshes were drained; some were maintained by landowners as sources of wildlife for food. Since new monasteries were often built in remote locations, monks contributed not only to clearing land but also to developing more robust strains of fruit, especially grapes, that could survive the cooler northern temperatures.

Processing of the Roman-era staples of wheat, millet, and barley, the cheapest grain, became faster thanks to the spread of watermills. Water-powered mills freed up time previously spent grinding grains by hand or by animal-powered mills.

Early Medieval Chinese Agricultural Technology

Throughout this era (300–1000 CE) and indeed for most of the last 3,000 years, Chinese agriculture led the world in productivity. The Chinese cultivated a wider variety of crops than most other peoples. The Chinese speak of the five

grains that for centuries have been their staples: rice, wheat, barley, millet, and kaoliang (or sorghum), but actually they had many more. There were several species of millet, for example, each adapted to a specific type of soil and weather pattern. The Chinese had crops that were suitable for a wide variety of soil conditions—arid soil, swampy soil, clay, sand, slightly saline soil, etc.—and so their agriculture was able to thrive in a wide variety of ecological regimes.

In addition to the wide variety of grains, which in every age provided the bulk of the food for the Chinese people, the Chinese also grew a great diversity of fruits, vegetables, and legumes. Pears, peaches, plums, apricots, and jujubes were grown in the north, while oranges, lemons, bananas, lichee nuts, and other tropical fruits were produced in the south. Mulberries were widely cultivated for their leaves to feed silkworms rather than for their fruit. Many vegetables were grown for both their roots and leaves. Legumes were widely cultivated both for their nutritional value and their soil-amending properties. Adzuki (red) beans were a favorite, and broad (fava) beans were introduced from West Asia around the fifth century CE. But the most widely cultivated and eaten legume was the soybean.

Soybeans can be eaten raw or processed into a variety of forms, including the Chinese staple bean curd (tofu), and preserved easily. It is a hardy plant that can tolerate extremes of climate, drought, mildly saline soils and other adverse conditions. Soybeans, introduced into the valley of the Yellow River around the seventh century BCE, were probably domesticated by Manchurian tribesmen from a plant that grows wild in northeastern China. Originally soybeans were used by the Chinese as animal fodder and as famine food, but by several centuries BCE soybeans had been naturalized in China and were a ubiquitous element in Chinese cuisine. Soybeans proved to be a wonder crop. Due to its high content of usable protein, soybean could replace most animal protein, making the reservation of land for the production of animal fodder and pasture less important.

These crops provided a more balanced diet on a smaller unit of land per capita than did other agricultural regimes, allowing for a more dense agricultural population. This in turn war-

ranted a much more intense investment of labor, which resulted in more enhanced production for each unit of land.

Most crops were for food, but some were also for fiber. Hemp was grown for both fiber and the oil from the seeds. Flax was cultivated for the oil in the seeds; the early medieval Chinese did not make linen. Other oil crops were rape, mustard, and sesame. Crops for fiber were silk, which was produced by the silkworms fed on mulberry leaves, hemp, and ramie in the south. Cotton was introduced from India around the fifth century CE and in time became the basis of China's leading textile industry. During the Tang dynasty, tea became an important crop in China's southeast and long remained a leading Chinese export.

In early medieval China, farmers employed a very wide range of cultivation systems that varied according to the terrain and climate. In the dryer north, their fields, although miniscule by Western standards, were usually rectangular. Since rainfall could be erratic in northern China, farmers developed a ridge and furrow tillage system that could save the crops by draining off water in times of excess rain and preserving moisture in times of drought. To construct the ridges and furrows, farmers, probably before the Tang dynasty, developed an implement pulled by oxen, called the butterfly winged hoe. (During the agricultural revolution of the eighteenth century, British farmers replicated this Chinese invention, possibly from Chinese models. It is known in the West as the horse hoe.) On these fields, early medieval Chinese peasants planted wheat, barley, millet, or another grain, using a mechanical seed drill to distribute the seed evenly in the rows. (Seed drills were not used in Europe and America until the eighteenth century CE.)

In more arid areas or in cases in which early or late frosts were a danger, Tang farmers employed pit cultivation. In this system, farmers dug pits, whose size and spacing depended on the crop and whether the purpose was to conserve moisture or to provide a warmer microclimate for the plants. Into the pit the farmer would usually deposit composted straw and manure as well as the started plant.

On hillsides, terraces to prevent soil erosion and to conserve moisture were laboriously constructed. In many cases, these terraces could be

flooded to grow rice. In the Yangtze Valley and to the south, much of the land was devoted to rice paddies. Rice paddies are among the highest-producing types of agriculture, but their construction and maintenance are extremely labor intensive. First, the land in each paddy (according to Chinese agronomists, the optimum size of a rice paddy is one-sixth of an acre) must be leveled to within an inch so that the rice plants can be evenly covered with water. Berms, or earthen dikes, must be built to contain the water; the paddy must be flooded and drained several times a year for planting, cultivation, and harvesting. Before the transplanting of the rice, the paddy must be plowed several times. In the Tang dynasty, Chinese peasants were using iron plows with curved moldboards pulled by an ox or water buffalo. This was a type of plow not available in Europe or America until the nineteenth century. After plowing, the paddy was flooded, and the rice seedlings, which had been started in a special and smaller starting bed, were transplanted by hand in rows in the paddy's mud. Usually the laborer did this by stooping, but sometimes the peasant built a raftlike tool that carried the unplanted seedlings and on which the worker could sit while transplanting. After planting the grain crops, whether rice, wheat, or other, the farmer hand weeded the plants. This was also labor intensive, though between the rows a hoe, usually of cast iron, could often be used.

In early medieval China, in contrast to Europe and the Mediterranean region, land was rarely left fallow. Multiple annual cropping was the rule. Two crops were the rule in the north, but sometimes as many as four could be har-

vested in the south. Care was taken to alternate crops such as rice or wheat with crops such as soy or adzuki beans so that the fertility could be maintained. Often, bean and rice stubble was plowed in as a kind of plant manure. Early medieval Chinese peasants were careful to manure their fields with chicken or pig manure and even human night soil. Silkworm droppings were a very highly valued fertilizer.

Animals were not allowed to roam freely in pastures but instead were kept in pens or special enclosures to prevent them from injuring the fields and to preserve their valuable manure. Oxen were fed the straw of rice, wheat, or other grains as well as the stalks of soy and other beans. Periodically, often daily, these animal pens were cleaned, and the manure was kept in special manure containers, where it was mixed with plant compost and mud.

Early medieval Chinese farmers used tools made of iron more often than any of their contemporaries in both the Eastern and Western Hemispheres. In some dynasties, the making of iron tools was a government monopoly. These tools were a further element in enhancing the output of the peasants' labor and thus early medieval Chinese agriculture.

■ Introduction: Early Medieval Industrial Technology

During the Era of Expanding Regional Civilizations (300–1000 CE), levels of industrial technology varied from civilization to civilization but nevertheless exhibited some similarities throughout the globe. The making of pottery and ceramics was nearly universal among sedentary peoples and very widespread

among nomadic hunters except in Australia. Some peoples, such as the Eastern Polynesians and the Inuit, abandoned the making and use of pottery because of the lack of suitable clay or fuel. Other groups, such as most of the North American peoples, adopted the bow and arrow from the Arctic peoples during this era.

By the beginning of this era most peoples in Africa were smelting iron and making iron tools, weapons, and ornaments. During this era, iron production became a central economic activity for many groups, and among some West African peoples iron smelting and ironworking were the jealously guarded preserve of a prestigious blacksmith's caste. These smiths made not only tools and weapons but also ceremonial items, such as the widely traded clapperless double bells, made of iron sheets bent into the proper shape and the forge welded together.

Another widespread technology in Africa south of the Sahara was copper smelting and working. Copper was used for ornamental jewelry as well as for money, with pieces of copper cast in the shape of crosses or the "X." Much copper was also used in West Africa for producing brass to make sculptures and other artwork.

In Mesoamerica for most of this era, one of the most highly developed technologies was the creation of stone tools and ornamental work. This was done both in chert, or flint, and obsidian. Although bronze metallurgy had diffused north through Central America perhaps before the end of this era, obsidian remained the favored material for weapons and tools in Mesoamerica.

In the Andean region, metallurgy in arsenic copper as well as tin copper was highly developed. Andean smiths were adept in both casting and forging. Other important Andean technologies in this period were the production of cotton textiles with very intricate weaving patterns and the molding of highly fired ceramic sculpture.

Throughout Eurasia, almost every people practiced metallurgy, made pottery, and used the bow and arrow and/or crossbows. Three civilizations in Eurasia were technological innovators: those of China, India, and Dar al-Islam (the Islamic world).

For several centuries Chinese technology had been the most innovative in the world. Inventions and new techniques during this era commonly originated in China and diffused from there to India, central Asia, and the Mediterranean region.

India had a highly developed industrial technology probably as long as China's. Indian industries were organized into guilds, and these guilds proved very effective in training skilled crafts-

men in many arts, such as making steel surgical implements. India excelled in metallurgy, particularly the making of wrought iron and steel. Its steel longbows are said to be powerful enough to shoot a missile that could penetrate armor. Throughout this era, Indian smiths produced the world's finest steel. Swords made of India's Wootz steel took very sharp edges and were eagerly sought after by India's trading partners throughout the first millennium and after, from the Romans to the Arabs and then the Turks.

Indians developed and passed on to the Arabs many of their industrial processes, including the art of distilling alcohol from sugar. The Muslims took many of the industrial processes they adopted from India and China and adapted it to their needs, often improving on it.

The Europeans, whose industrial practice, like many other aspects of their civilization, had seriously declined since the fourth century, were on the western end of the technology transfer that started with China or India, went through Dar al-Islam, and finally reached Europe, usually after several centuries of delay. After the fifteenth and sixteenth centuries, Europe would catch up with and surpass the Muslims and the Chinese in technological innovation, but during this era Europe was a technological backwater.

—Wilfred J. Bisson

Technological Innovations in East, Central, and Southern Africa

In East, central, and southern Africa in this period, specific technological information depended on a person's gender. Women were the potters across most of the continent, whereas ironworking was almost exclusively a male technology. Following the adoption of an agricultural lifestyle, women controlled the technology of potting, agriculture production, and the preparation of food. The technology of potting had not changed significantly from its discovery circa 3000 BCE through this period.

The new technological factor in this period of the region's history was ironworking. Interestingly, the rituals, traditions, and cultural mores associated with iron production were based on the potting traditions that date back to a much earlier

➤ IRON SMELTING AND MOTHERHOOD

The manufacturing of iron items was the new technological innovation established during this historical period. While men were the main producers of iron, the spiritual beliefs, rituals, and even the ore used were dependent on female imagery and women themselves. Technology, like every other aspect of their societies, was closely connected to spirituality. In many parts of this region the iron smelters were gynecomorphic, which means that birthing imagery and words were used to equate the production of iron with childbirth. While some societies just used birthing terminology, others actually put breasts on their iron furnaces. Women were also the extractors of the iron ore. Osteological assessments of bodies found in ancient mines of east-central and southern Africa indicate that women were miners as long ago as 1,500 years. Women as miners fits into Bantu-speaking peoples' belief that women were responsible for all things from the earth such as clay, agricultural items, and even ore.

—Christine Ahmed-Saidi

period. In the potting rituals, only adult women gathered clay. Menstruating women were excluded from rituals, as were men and children. Potters were forbidden to have sexual intercourse with their husbands prior to clay rituals.

Iron smelting had similar prohibitions except in reverse. As in potting rituals, menstruating women were not allowed at the smelting site, and men were not allowed to have sexual intercourse with their wives prior to smelting iron.

Ironworking technology became a shared feature of societies in the western Great Lakes region of East Africa. From there it spread west into the equatorial rain forest and east and south in East Africa. Ironworking technologies were well established in east-central African regions by 300 CE. Linguistic data indicates that at this time there were terms for smelting furnaces and new words for a range of iron tools, from knives and spears to hoes and razors. Thus, ironworking technology was well known across the region. An axe, barbed arrowheads, a curved knife, a spearhead, and possibly an iron hoe were found in eighth-century CE graves in the Congo. In

other graves dating to approximately 900 CE, smelted copper items have been found in addition to the iron objects.

An interesting element of iron-smelting rituals during this and later eras in central Africa and parts of East Africa was the distribution of overtly gynecomorphic iron-smelting furnaces. The individual furnaces were referred to as wives, initiated young women, or mothers. Some furnaces even had breasts or were set up to mimic the position of a woman giving birth. The process of iron smelting contained all the metaphors for birth, and iron processing may well have been seen metaphorically as a male version of reproduction.

In northeast Africa around 800 CE, it was not the Bantu-speaking peoples who were the iron producers but instead the Gumba, a group of Southern Cushites living around Mount Kenya. Among other Cushitic-speaking people, both potters and iron smelters formed separate castes. Members of these castes were eventually considered inferior to other workers, which was in direct contrast to the high status of blacksmiths and iron smelters in later Bantu-speaking states.

During this historical period Bantu-speaking peoples began producing iron jewelry, iron ritual items, and iron fishhooks. Male control of ironworking meant that smiths produced the iron tools needed by both men and women. A highly important new tool of cultivation, the iron hoe, was invented in the first millennium BCE. The hoe spread widely in the later last millennium BCE in East Africa and probably from east to west across east-central Africa by 300 CE. This new tool, specifically designed for women's farming work, enhanced women's capacities for digging savannah soils and preparing fields for grain cultivation. But in adopting the hoe, women's productivity in agriculture came to depend for at least one essential tool on a male-produced item.

Chinese Technology

It has often been said that until the fourteenth century CE China was the most technically advanced civilization in the world. Certainly, China has been credited with a number of technological firsts, especially the so-called big four: the compass, paper, gunpowder, and printing. But it is the sheer volume of its technical advancements and innovations that places China at the top of the list. China's standard written language and its social stability allowed it to undergo dynastic changes without great technological loss. This allowed the Chinese to continually build on previous innovations without having to repeatedly reinvent the wheel. Chinese technology also developed mostly within the official networks of government-controlled industries, factories, and workshops, and beneficial technologies were cultivated and dispersed through these same networks.

The big four—the compass, paper, gunpowder, and printing—had tremendous impact on China but were also extremely important for the development of Western cultures, including Europe and the Islamic world. Arab and then Muslim mariners were visiting China for trade from the beginning of the first millennium. There they may have picked up the technology for the compass. Although critical for navigation, the compass also played an important role in the Islamic religion, allowing followers to pinpoint the direction of Mecca for prayers. Paper allowed Muslims to develop huge libraries, as it cut the cost of producing books dramatically. This also helped to increase literacy in the Islamic world and to spread new technologies and ideas there as well. Printing with movable type did not appear in Europe

until the fifteenth century, but it arrived at a particularly important point in history. The new presses and Europe's discovery of paper technology increased literacy and helped fuel the Reformation and the Enlightenment. At about the same time the Islamic world was exposed to the new printing press technology, but rather than embrace it, as had Europe, they banned it. Islamic authorities feared that the press could defile the name of God and make it easier to distribute undesirable writings. Gunpowder was developed in China in the ninth century and was used for military purposes from the mid-1200s. At almost the same time Muslim armies, which had received gunpowder technology from China, used gunpowder against the European crusaders. Gunpowder then moved into Europe, where it revolutionized warfare. The first cannons were developed there around 1310 and spread to the Muslim world by the 1330s, and by the 1350s the Chinese had received the technology from the Muslim world. The circle was completed.

Other than the big four, the vast majority of China's inventions have been less well known. Many are in the area of agricultural production, but their technological processes were often modified for use by other industries, and as in Western industrialization, a speed-up in one area of production led to innovations in others. For example, water-powered trip hammers for husking rice were invented during the Han dynasty. By the first century CE this same technology with heavier hammers helped improve the production of iron and steel. To keep up with rice husking by machine, the Chinese soon developed a manually operated winnowing machine that separated the chaff from the grain. As production increased, the need to move more grain more efficiently led to the wheelbarrow. Unlike the European wheelbarrow, the Chinese version had the wheel placed directly under the load, which allowed the operator to move heavy loads of up to 300 pounds with little effort.

Rice farming required irrigation, as did farming in more arid regions. Machines to move water from one level to another for irrigation would later find applications in mining and hydro-engineering. Chain pumps consisted of an inclined trough with the lower end placed in the water and the higher end placed where the

➤ WHY WERE THE CHINESE SO ADVANCED?

What made the Chinese so technologically advanced for their time, and what allowed them to hold on to that position for almost 1,000 years? One key component of the answer is population. China had nearly one-quarter of the world's population under the same government and same written language. China's intense urbanization helped concentrate the population into smaller and smaller areas. The middle class that arose in these cities helped to commercialize agriculture, increase trade, and expand manufacturing. This meant more support for innovation and technological improvements, although during the Song dynasty the Chinese bureaucracy began to limit the development of technology outside of government channels.

Another component of China's technical position was the government, which monopolized many areas of production and promoted and supported technologies that increased production. Many early innovations were tied to agricultural production, essential for feeding the growing population. The government encouraged agricultural innovations as well as others such as calendrical astronomy and mathematics that were beneficial to the government.

There are many other factors that could have promoted technological development. The single writing system in place since the fourth century BCE and the early development of printing from carved blocks allowed information to be spread throughout the educated classes quickly and inexpensively. This also helped promote the spread of technology, as did the relatively stable social and political climate of China. China's canal system, which was over 31,000 miles long by 1200, also helped spread inventions and ideas. Maintaining the canals helped advance hydraulic engineering. Also critical was China's early mastery of metallurgy and especially the production of iron, which were needed to produce many advanced machines. Other possibilities include China's diverse diet, which had few restrictions, and the use of vegetable proteins. Or could it have been, after the Tang dynasty, the drinking of tea? Boiling water to prepare the tea killed many hostile organisms in the water and has been credited with the longevity of China's people, or perhaps it was because China's culture was more open to cleverness and invention. The entire answer may never be known, but it cannot be denied that by the year 1000, China was still the master of the technological world.

—Rebecca Wendelken

water was needed. A mechanism moved a chain or series of closely fitting wooden paddles up the trough, pulling the water along with them. At the upper end the paddles passed over a wheel, dumping the water into a ditch or container, and then the paddles continued down the underside of the trough to repeat the process. This primitive pump could raise water to a height of about 15 feet. Vertical water-powered bucket wheels, similar to those developed in the Middle East and brought back to Europe by the crusaders, also moved water from one level to another. Bamboo or wooden buckets filled with water from a flowing stream at the bottom of the wheel and moved upward to be dumped onto a flume at the top of the circuit. This mechanism was later used to harness the power of flowing water for driving other machinery. Specialized tools for particular jobs were also invented in-

cluding, in the Tang dynasty, a harrow and special plow for use in the wet-rice fields.

Sharper and more efficient cast iron agricultural tools developed as early as the fifth century BCE but were not widespread until the Han dynasty. By China's medieval period the earlier simple iron plows had developed into pointed iron plows with sideboards and adjustments that optimized their efficiency in different soil conditions. These new plows were especially important for expanding agriculture into China's northern border regions. Better plows needed more power, and new techniques were developed for harnessing oxen and horses to optimize their ability to work. With more land under cultivation, the old method of broadcasting seed was no longer efficient. By the beginning of the first millennium, multitube seed drills that could dig multiple furrows, distribute the seed, and

cover it over with soil—all in one operation—were in use. Crops planted in rows were easier to hoe and to irrigate. Irrigation technology was used on a larger scale to build a system of canals that crisscrossed China and made shipping raw materials and finished goods more efficient and less costly.

China mastered bronze smelting and casting early in its history, and this paved the way for the development of the iron industry, which came under state control as early as 117 BCE. Innovations increased production so that by 806 CE China produced some 13,500 tons of iron a year. This figure continued to increase due to innovations such as the open hearth furnace, an ancestor of modern smelting processes. By the eleventh century production had been raised to 125,000 tons a year. When massive production put a strain on local resources for charcoal for the smelting process, China turned to pit coal and finally discovered that by preheating the coal to drive off impurities they could achieve even higher temperatures. This was the first use of coked coal. The improved smelting processes also used water wheels from agriculture to drive double-action piston bellows, also raising smelting temperatures. The same technology was later used to pump water and as a flamethrower. These new piston bellows were made possible by the invention of reduction gears that were soon applied to other inventions, including the odometer cart for measuring distances. These set the stage for mechanical escapement processes in the eighth century that allowed the development of mechanical clocks and machines that replicated celestial movement. Armillary spheres used to determine the position of celestial bodies reached their height of development in the tenth and eleventh centuries and could be set in motion by water power.

Mining techniques also improved to feed the growing iron and steel industries. Pumps used in agriculture could also be used to dewater deeper shaft mines, while iron tools and the wheelbarrow made removing and transporting the ore more efficient. The components of gunpowder were adjusted to make a more explosive product. This was used in mining for blasting. The Chinese not only used pit and shaft mining but also developed deep-well salt mining. Stone

and later steel drills were used to tap underground salt brine. The brine was brought to the surface with pumps and then dried to make salt.

In textiles, advances in silk production and manufacture helped create what for centuries was one of China's most valuable exports. Even after Western regions such as Byzantium developed their own sericulture, they were still reliant on China for much of their raw materials. Water-powered reeling machines were used to unwind the silk filament from the cocoon. The oblique loom, which used wooden shafts and treadles to facilitate forming patterns in fabrics, developed during the first century CE. Similar looms were not used in the West until the thirteenth century. Upright treadle looms developed before the tenth century and allowed even more complex fabric patterns to be woven in less time.

Even China's geography provided impetus for invention. Because the country was located near fault lines, early China was interested in lessening the destruction of earthquakes. In the second century CE China developed an early seismograph. This ingenious device consisted of a heavy pendulum inside a closed bronze urn. When a tremor occurred the pendulum swung, releasing one or more brass balls in the direction of the quake. Sometime before the fifth century China also developed the *dougong*, or bracketing system, of building in which an interlocking system of members supporting the roof dampened the energy of the earthquake as it traveled up the pillars supporting them. As bridges were especially vulnerable to quakes as well as floods, more stable bridges using segmental arches instead of semicircular ones were developed in the seventh century. The first of these is still standing intact today.

As can be seen by just these few examples, inventions such as these put China technologically ahead of Europe by as much as 1,000 years. The early beginning of technological progress and the large number of practical inventions make China the world's first technological civilization.

Early Medieval Islamic Industrial Technology

Dar al Islam was, after China, a leading center of innovation in industrial technology in the early medieval age. The Islamic world developed its industrial techniques, building on the industrial heritage of the Persians, the wealthy West Asian provinces such as Syria that it conquered from the Roman empire, and the Egyptians. These areas already possessed a rich and highly skilled industrial base, and the Muslims added to this base by adapting new technological advances from India and China, which Muslim scientists and technicians further developed into innovative industrial methods. The Muslims developed industrial centers in Syria, Baghdad, Egypt, and Spain at which they produced cotton cloth, glass, paper, and fine steel using processes they adapted from the Chinese and Indians.

The Muslims learned papermaking from the Chinese, reputedly from Chinese soldiers taken prisoner at the Battle of Talas in 751, but the paper they learned to make, though very usable for Chinese brush strokes, was too soft for the Muslims to write on with their quill pens. The Muslims discovered that if they added starch in the papermaking process, the paper would withstand their more energetic writing method. The Muslims learned to refine sugar from the Indians and developed water-powered sugar mills for that purpose.

It is sometimes said that the Muslims learned of water mills and windmills from the Chinese, and it is possible that they got the idea of these mills from the Chinese, but the windmills and water mills developed by the Muslims (and subsequently passed on to the Europeans) were

new inventions. Whereas the Chinese used horizontal water wheels and windmills, those that the Muslims developed were vertical like the irrigation wheel already used by the Egyptians for centuries. The Muslims invented crankshafts and gear trains to transmit power from these mills, and they also developed new machines, such as the water turbine, along with dams to store waterpower.

Egypt was the home of an ancient glass-making industry. After the Muslim conquest, Egyptian glasswares found markets not only throughout the Arab Muslim empire but also in all the lands with which Muslim merchants traded. Large factory-scale glass-producing establishments grew up in Lower Egypt to satisfy the growing demand. In the early Middle Ages the Muslim world had the world's largest glass industry. Pottery was another highly developed industry. Although the Muslims never learned the secret of making porcelain, they did make lusterware and stoneware that was nearly vitreous and looked like porcelain. Muslim potters also were the first to produce tin glazed pottery, which the Byzantines learned in the ninth century.

Muslim technologists improved on the distillation process they learned from India. They not only made alcohol from sugar, as the Indians did, but also pioneered in dry distillation and steam distillation and invented new tools, such as the alembic and retort for the distillation process. Using distillation techniques, they learned to make kerosene for lamps and naphtha and asphalt from the crude oil they extracted from the oil fields near Baku on the Caspian Sea. Some of the streets in Baghdad, it is reported, were paved with asphalt produced by distillation.

Muslim scientists led the world in refining new chemical and mineral products. The eighth-century Baghdadi polymath Jabir ibn Hayyan (known in Europe as Geber), whom some liken with the American Thomas Edison, discovered the elements arsenic and antimony and produced many industrial chemicals such as alkalis, acids, borax, ammonia, and ethanol.

In metallurgy, the Muslims were behind China and India. The Chinese made cheaper and more abundant cast iron, and the metallurgists of southern India made the world's finest steel, Wootz steel. In the tenth century, Damascus

smiths began to make fine Damascus blades, using materials derived from India. Later other centers, such as Toledo, also used that process.

Early Medieval European Industrial Technology

Economic decentralization led to industry on a smaller scale than had been practiced at the height of the Roman empire. Weaker trade networks, resulting from political instability, made local manufacture and self-sufficiency much more important. Carthage, for example, previously imported ceramic lamps from stylish Rome; by the 360s, Carthage made its own.

In the fourth century, towns and cities across the Roman empire were increasingly building walls, earthen and stone, to protect themselves from political unrest and invasion. These large local building projects were increasingly typical of construction in the early Middle Ages. Stone quarrying provided some of the building material, with timber farming comprising most of the rest. The products of brick kilns were also used in building projects. Iron smithing provided nails, hammers, reinforcement for shovels, brackets, and other tools critical to building projects.

Mining, smelting, smithing, and all the other trades involved in metal production declined over the early Middle Ages due to scarcity of new mines. Mining provided the raw materials from the earth: iron, copper, tin, gold, and silver. Smelting was the process of extracting each metal from the stone or earth in which it was mined. Smithing processed the metal into a usable form. Iron was a staple metal, used for arms, armor, knives, pots, pans, horseshoes, and reinforcing farm tools such as the plow, scythe, and hoe in addition to building tools. Rotary grindstones, for sharpening blades, were known in Europe by 834, when one was drawn in the

Building the Ark. Detail from scenes of the Old and New Testaments, Byzantine ivory plaque, ninth century CE. Depicted are typical early medieval tools: saw, axe, adze, drill and the like. (Erich Lessing/Art Resource, NY)

Utrecht Psalter. Both gold and silver were more often reused than mined. Gold was preferred for coins and jewelry, while silver was more difficult to smelt but was more widely available.

Water mills, developed in the first century BCE, were large machines with a local market. Although they were the largest and most sophisticated machines produced by the period, they supplied water power to a task that provided sufficient ground meal only to its own greater vicinity. Grain, once ground, does not keep as long. Most millstones in northern Europe and the British Isles were imported from around the Rhine. Their numbers grew over the course of the early Middle Ages, supplemented throughout by other forms of milling: hand mills and animal-powered mills. Fabric production, from flax or wool, was also usually local, with the occasional expensive import of silk or cotton from the East. Many bone tools were made for the textile industry. Manufacturing operated on larger scales only when coordination and funding existed for it. Justinian could afford to hire 10,000 men to build Hagia Sophia, beginning in 532, because the Byzantine empire was more centralized and cohesive than the other successors to the Roman empire were.

In the fifth century, monasteries began to be alternate centers of industrial production. Intended to be largely self-sufficient communities, overproduction of goods, such as tanned hides or fulled fabric, enabled a monastery to trade for the goods it needed. By the eighth century, ship trade across the North Sea was expanding along with the production of wool, timber, iron, beer, and wine. Salt furnaces extracted salt from sea water for trade. Pottery, glassmaking, tanning, and beer and wine production were also important industries. More pottery has survived from the early Middle Ages than any other kind of

good. The earliest known application of mill power to something other than grinding was in 990, when the first animal-powered hemp mill is recorded. From local, defensive, decentralized pragmatism in the fourth century, European industry had begun to redevelop its trading networks and with it larger-scale, more mechanically based industries.

Early Medieval Metallurgy

One of the basic technologies in any human society concerns the materials for tool and weapons making. During the first millennium CE, most civilizations in the Eastern Hemisphere fashioned tools and weapons using metals, although some in the Far North and Africa south of the Sahara still relied on stone, bone, and sinews. In the Americas, the Andean peoples used metals, primarily copper alloys, for tools and weapons. Although the Mesoamericans knew of metallurgy, metals were used mostly for ceremonial and decorative purposes; the Mesoamericans preferred obsidian for utilitarian devices.

In the Era of Expanding Regional Civilizations, seven metals were known: copper, mercury, gold, silver, tin, lead, and iron. Other metals were often used, but they were used in compounds and were not usually identified.

Antimony compounds were used to make cosmetics, particularly kohl, and (very rarely) to plate copper vessels. Arsenic was used in West Asia and Egypt to make bronze alloys in the early Bronze Age, but after tin became available arsenic was used only rarely. Andean metallurgists made bronze with arsenic along with tin. Arab alchemists isolated arsenic in the eighth century, although the Persians before that knew native arsenic. The Muslim alchemist Jabir ibn

Hayyan separated bismuth from lead in only the eighth century, but the peoples of the Andes knew of bismuth and produced a copper-tin-bismuth bronze for making sharp-edged tools. The Chinese as early as the Qin dynasty (third century BCE) sometimes used chrome to plate their bronze crossbow bolts and swords. The process they used is not known, nor is it known how long that practice continued.

Zinc was not recognized as a separate metal, although alloys of zinc-lead and zinc-iron-copper were sometimes used. It was not until the end of this era, circa 1000 CE, that zinc was smelted in China and India.

The early medieval Eurasian alchemists classified the known metals into noble and base metals. Mercury, gold, and silver were noble, while copper, tin, lead, and especially iron were base. Mercury was used sometimes for cosmetic and medicinal purposes. Gold, silver, and copper and sometimes iron were used in coinage. The Chinese produced cast, not stamped, coins of copper, bronze, or silver. In the Muslim world and Europe, pieces of gold or silver were stamped, not cast, as coins. In India, gold, silver, and copper were all used in stamped coinage. In central Africa, cast crosses of nearly pure copper served as currency in the second half of the first millennium CE.

In the Afro-Eurasian ecumene, gold was highly valued. Much of the gold that entered the currencies of this ecumene originated in the West African forested region and was then transported by camel caravan across the Sahara Desert. The Southeast Asian peninsula was another important source of the precious metal during this era. In the Americas, especially in the Andes, gold sometimes served as a quasi-utilitarian metal, used in certain elite vessels as well as for jewelry. Metallurgists in the area spanning the Andes and Central America sometimes produced an alloy including gold, copper, and sometimes silver. This alloy, tumbaga, varied in hardness with the ratio of copper to gold it contained and was used for jewelry, some ceremonial cups, and other utensils as well as some tools.

Unalloyed copper was used widely not only for coinage but also for jewelry and utensils. But the chief use of copper was in alloys as bronze or brass. In the Afro-Eurasian ecumene, bronze was seldom used to make weapons or tools dur-

THE MYSTERY OF THE IRON PILLAR OF DELHI

Chandragupta II (375–414 CE), one of the most powerful emperors of the Gupta dynasty that ruled northern India (280–550 CE), erected a 23-foot-high cylinder of remarkably pure wrought iron on a hill situated on the Tropic of Cancer in the center of India. The pillar was made in sections that were joined by forge welding, a process that required a degree of heat obtainable by burning coal. It weighs more than 6 tons (12,000 pounds).

Thought to be a center from which emanated great spiritual power, the site on which it was erected was called the Hill of God's Footprint. The pillar was erected as a gnomon, or sundial. The shadows that it cast were said to exert mystic power.

About 800 years later, Muslim conquerors, impressed with the huge iron shaft, transported it to Delhi, where they had made their capital. There, they gave it a place of honor in the park of great monuments, the Qutb Complex. The pillar never rusted, astounding the world with its purity. The pillar attracted pilgrims who believed that if they stood with their back against it and were able to touch their fingers of the opposite side, they would have luck.

In the 1990s, experts have discovered the secret of the pillar's freedom from corrosion. The Indian master iron makers who smelted the ore to make it used wood with high phosphorus content.

The Iron Pillar made by Indian iron mongers in the fourth century CE in central India and moved to Delhi by Muslim rulers in the thirteenth century. (Alicia Nijdam)

The phosphorus in the metal creates a microscopic film that prevents oxidation.

—Wilfred J. Bisson

ing this era, but it was more widely used to cast statues and ceremonial objects. In the Andes, metallurgists alloyed copper with arsenic, tin, silver, bismuth, and other elements to produce a wide variety of bronzes. The Moche Valley was one of the most dynamic sites for metallurgical innovation, and its craftsmen were working with many bronze alloys for both forging and casting knives, chisels, hoes, and needles. Their cast bronzes often included up to 2 percent arsenic. In Tiwanaku in the southern Andes, tin alloyed bronze was the all-purpose material for many tools and weapons. Their cast bronze generally had a high tin content (10–15 percent), while their forged tools and weapons were commonly made of low tin-bronze.

Mochica metallurgists concentrated on forging (i.e., hammering heated metal into shapes),

while the Chibcha of Colombia were more apt to cast the metal in a foundry.

Chibcha metallurgists cast decorative items of tumbaga using the lost wax process. This gave copper more hardness and luster.

Metallurgy, other than the cold forging of native copper and gold, did not become an aspect of Mesoamerican culture until late in this era. It is commonly thought to have diffused north from the Andean region through Central America and, perhaps, by coastal trade on the Pacific littoral from Ecuador to western Mexico (Colima), where casting of copper alloys (tin and arsenic bronzes, tumbago, or gold, silver, and copper alloys) was apparently adopted by 800 CE. But after metallurgy was adopted in Mesoamerica, it was used largely for production of ceremonial and decorative objects and very little for tools and weapons.

The reason for this was the abundance of and ease of working obsidian, a type of volcanic glass. Tools and weapons with very sharp cutting edges, superior to anything the metallurgists could produce, could easily be fashioned in Teotihuacan and the numerous Maya cities.

In Africa south of the Sahara, brass, a copper-zinc alloy, was used to make artistic and ceremonial objects.

Tin was one of the essential elements in bronze alloys; the other was arsenic. Tin was relatively scarce in Europe, the Mediterranean basin, West Asia, and India, but it is much more abundant in China and Southeast Asia. Although the chief metal in tools and weapons in this era was iron, tin was still used to make some bronze tools but mostly for bronze in statues. Tin was also used to make pewter for elite tableware and utensils. The chief source of tin in Europe was cassiterite from Cornwall, England.

Lead was widely used for water pipes and containers. By the eighth century, silver with lead was being mined in the Rhine Valley, the Harz Mountains, and central Asia as well as numerous sites in China. Most silver was a by-product of copper, gold, lead, and zinc refining.

During the early medieval age, southern India led the world in the production of steel, the most developed form of iron technology, while China had the most productive cast-iron industry. Europe and Africa south of the Sahara as well as the Muslim world produced relatively soft and inferior wrought iron until the ninth century, when the Muslims learned more effective steel production from southern India.

The softest and most technologically simple iron was the wrought iron produced in the west: Europe, Africa south of the Sahara, and the Muslim world. In producing wrought iron, the ore is heated by charcoal to a point slightly below the melting of iron. To reach this heat, air must be forced in the mixture, which originally was done by a hand-operated bellows. Much of the impurities in the ore would melt, leaving a mass, or bloom, of metal mixed with some impurities. The bloom was then forged, or hammered, to remove more of the impurities. This produced relatively pure but also relatively soft and malleable iron suitable for tools, but for weapons that required a sharp cutting edge it was inferior to steel.

The Chinese preferred to produce massive quantities of cast iron by using blast furnaces, which they invented in the last centuries BCE. In their blast furnaces, they injected powerful jets of air by using waterpower, transmitted by horizontal waterwheels. The heat produced was sufficient to melt both the impurities and the iron. When the iron was melted, it absorbed larger quantities of carbon, which produced a rigid but brittle product. Although cast iron was, like wrought iron, inferior to steel for cutting weapons, cast iron tools and implements could be made more cheaply than wrought iron tools because the arduous process of forging, or hammering, could be avoided. Toward the end of this era, the Chinese began to use trip hammers, powered by horizontal waterwheels, to make the production of wrought iron less labor intensive. The Muslims and Europeans developed their own water-powered bellows and trip hammers, using vertical waterwheels, early in the second millennium CE.

Both Chinese and Western iron making used large amounts of wood charcoal, resulting in deforestation of large areas. In the tenth century, Chinese iron smelters discovered the coking process that enabled them to use coal in smelting. In the coking process, coal is roasted, driving off sulfurous and other gasses, leaving coke, composed of almost pure carbon.

India, in this era, had what may have been the technologically most-developed metallurgical industry. Indian metalworkers produced a type of wrought iron that was superior to that produced by the surrounding civilizations. Some historians maintain that the flowering of southern Indian as well as classical Gupta civilization was facilitated by the superior quality and abundance of their iron tools. The Indians also made the best steel in this era.

Indian steel, also known as Wootz steel, is still rather mysterious. Developed in southern India in the last centuries BCE, Wootz steel was forged into very sharp and supple swords that the Romans, the Chinese, the Muslims, and others eagerly sought. Wootz steel was crafted of iron smelted of ores containing trace amounts of tungsten, vanadium, and perhaps other elements. Two kinds of iron products were produced: a soft wrought iron and a harder iron that contained more carbon. Strips of both of

these products were laminated together, and in a process of alternate heating and cooling combined with hot and cold forging, blades were produced that had the suppleness of spring steel with the capacity of holding an exceedingly sharp edge. That the Muslim armies possessed swords made of Wootz steel may have been a factor in their successes in this era. By the tenth century the Muslims, using raw materials imported from southern India, were able to nearly replicate the Wootz process and produce the famous Damascus steel. They continued to produce superior blades of Damascus steel until the seventeenth century when, inexplicably, they abandoned the process. It has been suggested that the industry withered because southern Indian ores were no longer available.

Industrial Technology in Early Medieval Africa South of the Sahara

By 300 CE, societies in sub-Saharan Africa had developed an indigenous industrial technology that included a metallurgical tradition in iron and copper smelting and the casting of brass. Before 300, this region was already actively producing clothing, farm implements, and cooking utensils. There is archaeological evidence of the production of clothing through findings related to narrow loom weaving, ironworking, and wax castings. Innovations in transport technology during this period were a huge asset to craftsmen in that it allowed for greater trade with other world regions. Trans-Saharan and trans-Savanna trade routes allowed for the exchange of these commodities with the Mediterranean and Indian Ocean littoral. The incorporation of camels from Arabia allowed for their usage as pack animals within Africa. Camels carried goods

DEVELOPMENTS IN AFRICAN TECHNOLOGY AND CULTURAL RELATIVISM

Ethnocentric assumptions in the West have typically created a false view of Africa as uninventive and backward. Common misperceptions have been shaped by the absence of the plow for cultivation, little technology in maritime crafts, and the simplicity of African iron tools, among other issues. However, anthropologists and archaeologists of sub-Saharan Africa have illustrated through their research that such views are short-sighted given that social and economic conditions shaped African technological developments. Sub-Saharan Africans already had their own set of innovations that matched their needs and should be understood through their own culture rather than compared with innovations elsewhere. Technological development occurred as was necessary for the implementation of agriculture and industry. Such needs and growing contact with other world regions had a significant impact on such technological developments. Moreover, while contact with Arabs and the greater Muslim world already existed in much of the medieval period, much of their technology was invariably the same. African technology was shaped by local necessity, given regional foods, shelter, clothing, and religious observances. Some of their technologies were developed independently of other world regions, while some were as a result of increased contact through trade networks. Therefore, while awareness of external developments of technology did exist, the maintenance of regional technology rested on local needs.

—Tolope Lawrence Akinbogun

from Somalia to Sudan and well into regions along the Niger River. The incorporation of the camel allowed for the development of a network of caravan routes across the Sahara Desert.

Sub-Saharan Africans probably discovered iron smelting technology independently of influences from the Mediterranean region according to the evidence of linguistic analysis. Linguistic evidence also suggests that textile weaving on narrow looms was an indigenous development, although some scholars think that this technology might have been adopted from looms from South Asia. During this time, African weavers were mostly itinerants and needed more portable

equipment. The adoption of the narrow loom allowed them to have such equipment to carry out their craft. Nonetheless, as a result of this technological development, cotton cultivation and production as well as cotton-weaving technology grew in importance throughout sub-Saharan Africa.

In the region of eastern Nigeria, the Igbo-Ukwu culture is considered by scholars to be the most significant for technological development in this period. Artifacts of woven baste that were excavated by archaeologists in eastern Nigeria illustrate that weaving was an important industry by the ninth century CE in Igbo society. However, scholars are uncertain whether the looming process was in fact used for the manufacture of clothing. Cultural anthropologists, through comparisons with contemporary manufacturing of Nigerian mats, are convinced that this might be the case. Findings in Igbo-Ukwu culture also offer evidence of the production of beads in the southern Sahara. Beads of different colors were among other artifacts buried in this region that have been found in excavations. Approximately 165,000 stone and glass beads were found by archaeologists in the two excavation sites of the Igbo-Ukwu.

Ironworking was widely practiced in West Africa by 500 CE. The ore was either removed directly from hillside surfaces or dug from shallow pits. The ore was crushed between stones to remove the coarse impurities and overburden. The residue was then washed and placed in the furnace for smelting. The technology of the smith is a simple one consisting of elementary tools, usually the furnace, forge, and hammer. The *cire perdue* (lost wax) method of bronze casting was practiced by the Igbo-Ukwu in the ninth century CE.

The craft of pottery making was widespread in Africa south of the Sahara as it was in much of the world at this time. However, in this context it was a technology in which pottery was made by hand rather than with the use of the potter's wheel. While pottery was one of the oldest material cultures in Africa south of the Sahara, its practice from the Neolithic to the early medieval period continued without new innovations or technological changes. From 500 BCE to 200 CE, the earliest sculptures of terra-cotta yet dis-

covered in Africa were made. These were associated with Nok culture in northern Nigeria. The main techniques of building pots were pinching and coiling.

The potter's wheel was not used in Africa south of the Sahara until European colonization. Although there were different devices that could suggest the origin of the potter's wheel, these were not developed. While most pottery traditions in the world used one sort of rudimentary revolving device or another in the past, it was not known to have been developed in Africa south of the Sahara. Sub-Saharan African cultures began the production of large globular pots on the rounded bottom of previously fired pots; in some cultures it was started at the inside of a previously fired hemispherical pot. The devices were used as molds. The firing of pottery wares was done in the open in bonfires even though some rudiments of enclosed kilns were already in use in Asia.

The Invention and Production of Paper, 100–1000 CE — From China to West Asia

The invention and subsequent spread of paper profoundly altered the course of ancient world history, especially in the field of communica-

► CHRONOLOGY—THE DIFFUSION OF PAPER AND PAPERMAKING

- 140–87 BCE—First attested use of paper in Han dynasty China
- 105 CE—Cai Lun presented paper to Emperor He
- 0–200 CE—First attested use of paper for writing in Han dynasty China
- 200–300 CE—Paper reaches oasis cities of central Asia bordering on the Han empire
- 200–300 CE—Paper imported in states located on Korean Peninsula and in Vietnam
- 200–300 CE—Papermaking begins in Vietnamese territories
- 200–500 CE—Papermaking begins in central Asia
- ca. 280 CE—Paper replaces bamboo and silk in the production of Chinese books
- 300–500 CE—First attested uses of starches and dyes in papermaking in Chinese and central Asian territories
- 610 CE—Papermaking was introduced in Korea no later than this date; a Korean monk allegedly transmitted papermaking to the Japanese
- ca. 650 CE—Paper imported in Samarkand
- 751 CE—Muslim army captures Chinese paper makers at Battle of Talas
- 794–795 CE—Establishment of the first paper mill in Baghdad, capital of the Abbasid empire;
- widespread use of paper in the Abbasid bureaucracy
- 800–900 CE—Paper mills established in Damascus and other Syrian cities
- 800–900 CE—Paper imported in Egypt
- 900–1000 CE—Papermaking begins in Egypt
- 950–1000 CE—Paper imported on the Iberian Peninsula and used for the transmission of Muslim as well as Christian texts
- 1000–1050 CE—Papermaking begins on the Iberian Peninsula
- ca. 1050 CE—Paper imported in the Byzantine empire
- 1150–1200 CE—Paper appears in common use for commercial and legal transactions in northern and central Italy
- 1200–1250 CE—Papermaking begins on the Italian Peninsula
- 1300–1400 CE—Italian paper replaces Spanish paper in the Mediterranean and European trade
- 1400–1500 CE—Paper mills established throughout western Europe

tions. As a cheap and light material that could be manufactured in most places, paper gradually replaced most forms of media that societies across the world had been using for record keeping and the transmission of ideas since the fourth millennium BCE. Paper initially facilitated and expanded the use of written records in the Chinese territories beginning in the first and second centuries CE and, over the course of the first millennium, was adopted in East Asia, central Asia, West Asia, North Africa, and southern Europe.

Chinese historians and some Western historians following their lead have attributed the invention of paper to Cai Lun, a eunuch who served at the court of the Han dynasty and presented the new material to Emperor He in 105 CE. Twentieth-century archaeologists as well as authors contemporary to Cai Lun testify that paper was already in use by the second and first centuries BCE. Archaeologists date the earliest extant pieces of paper back to this period on the

grounds that the tomb in Baqiao (now Shaanxi Province) in which they were discovered in 1957 was sealed around the reign of Emperor Wu (140–87 BCE).

The materials and the procedures used in the manufacture of these early papers changed little over the course of the first millennium. The small pieces of paper discovered in Baqiao were made from hemp rags. Impressions on the surface of the paper suggest that the sheets had been dried on a woven mat. Paper was then, as later, made by beating rags or vegetable fibers, mixing them with water, and gathering the resultant pulp on screens from which excess water and pulp could be drained. The sheets of pulp were either left on the screens or suspended from walls or lines for drying and were thus transformed into paper.

Chinese artisans first used hemp and paper mulberry bark as their raw materials, but by the eleventh century their repertoire of raw

> CAI LUN

Cai Lun was a eunuch, or castrated attendant, serving at the Han court between the late first and early second century CE. He was one of the dozens of eunuchs in the service of the emperors Zhang (75–88) and He (88–105) and benefited from the rising political power of his kind, at the cost of the regular bureaucracy. For his alleged invention of paper, Cai was granted the title of marquis, and paper was known in Han times as “the paper of Marquis Cai.” This appellation was, if not a rightful attribution, a sign of the growing interest in paper at court and in elite society in the first centuries CE and of the technical improvements that court workshops may have realized under Cai Lun’s direction.

According to his biography *The Dynastic History of the Later Han Dynasty*, written by Fan Ye and completed around 445, Cai Lun conceived of a process to make paper from tree bark, rags, hemp, and fishing nets. He submitted his invention to the emperor in 105 CE and promptly received imperial recognition for it. This date should not be seen as the beginning of papermaking. Archaeological evidence and accounts dating back to the Han dynasty provide evidence for papermaking at least two centuries prior to the submission of Cai Lun’s invention. Nevertheless, the addition of organic materials may have been an innovation of Cai’s, as earlier papers appear to have been made from used products such as rags and nets only.

materials had expanded to include rattan, flax, ramie, jute, bamboo, seaweed, wheat stalks, rice straw, sandalwood, and hibiscus bark. Their extensive use of fresh plant fibers contrasted with later European manufacturing practices, which relied on supplies of linen and cotton rags obtained as a result of the growing popularity of

these textiles from late medieval times onward. Papermakers used two types of screens. The earliest papers were most likely made with floating screens. The papermakers poured pulp onto screens sitting on top of the pulp vat and peeled the sheets from the screens of woven ramie after all water had evaporated. Most extant Chinese papers were made with a second type of screen, the dipping screen, that allowed for faster processing. Artisans dipped the screen, typically made of bamboo, into the vat of pulp and transferred the wet sheets to boards or walls for drying.

In order to improve the quality of paper, Chinese and central Asian artisans began to add glues and starches either to the pulp or to sheets of paper between the third and fifth centuries CE. These glues and starches improved the cohesion of the plant fibers and rendered finished sheets suitable for writing or painting with ink. Around the same time, paper manufacturers began to experiment with dyes and colors. Some dyes were applied as insecticides, while others served purely aesthetic interests. The Han court began to use red and yellow papers by the third century CE. By Tang times (618–907) stationers supplied papers in ten different colors, ranging from apricot pink to light clouds.

The application of dyes and colors from the third century CE onward coincided with changes in the uses of paper. The earliest specimens of paper were blank. They were most likely used for wrapping. By the first century CE literate Chinese elites began to use paper as a substitute for less convenient writing surfaces such as wood tablets, bamboo strips, and silk rolls. Dyes and colors were an expression of their interest in the preservation of written materials and their desire for a luxurious and distinctive media of social exchange.

Once paper had been adopted as a medium for writing, it transformed the scholarly world. Sometime in the late second century or early third century CE, paper became more widely used than silk and bamboo in the production of books, as suggested by the Jin court’s decision in 280 CE to have its collections recorded on bamboo materials transcribed onto paper. Catalogs of the imperial collections of subsequent dynasties as well as extant records about private holdings indicate that from the third century CE onward

books in paper dominated court and elite culture. Paper became the ideal medium for the mechanical reproduction of texts after the adoption of woodblock printing in the eighth century. Even though its use for writing may have been most influential in the course of world history, paper changed the daily lives of millions of Chinese in other ways. During the first millennium it was used for such different purposes as fans, umbrellas, paper cuts, playing cards, napkins, lanterns, toilet paper, clothes, and harnesses.

The use and production of paper spread from the Chinese territories to all surrounding societies. To the west, paper reached the oasis cities of central Asia bordering on the Chinese empire by the third century CE and was manufactured there no later than the fifth century. It was imported in the rich city-state of Samarkand by the seventh century, and from there knowledge of the manufacturing process was further transmitted to Baghdad, Damascus, and other parts of West Asia. By the ninth or tenth century paper became known in North Africa, from where it was exported to the Iberian Peninsula in the tenth century. Long before its first introduction in Europe, paper had been in use in the societies of East Asia. Paper may have been introduced from the Han empire to states located on the Korean Peninsula and in present-day Vietnam as early as the third century CE. Vietnamese artisans learned the process of papermaking immediately, while Koreans engaged in papermaking no later than 610 since in this year a Korean monk allegedly transmitted knowledge of the process to Japan. This act of cultural borrowing was soon followed by the adoption of a related technology, woodblock printing, in both Korea and Japan. Thus, by 1000 CE paper had spread from China throughout much of the Eurasian landmass and in the process had revolutionized ancient communications practices.

Chinese Printing to 1000 CE—Technological Innovations and Their Cultural Implications

Printing, or the reproduction of images and texts by pressing paper against an inked surface, first emerged in East Asia when this region was culturally dominated by the Chinese Tang empire (618–907). Historians disagree on the questions of whether the invention of printing dates back to the seventh or the eighth century and whether Chinese or Koreans first mastered the technology. There is no doubt, however, that printing, predominantly with woodblocks, was used for a variety of purposes in East Asia centuries before printing spread to West Asia and the European continent.

The earliest surviving printed text that can be reliably dated is the *Vimala Nirbhaya Sutra*. This text, a Buddhist charm or dharani, was discovered in a pagoda in the Pulguksa Temple in Kyongju (South Korea) in 1965. It was printed from a woodblock onto a paper scroll sometime between 705, when it was first translated into Chinese by the Chinese monk Fazang (643–712), and 751, when the construction of the Sakyamuni Pagoda was completed. Only about two-thirds of the original copy, which may have been as long as

The world's earliest surviving book is a wood-block printed version of the Buddhist scripture known as the *Diamond Sutra*. The Tang dynasty-era sutra consists of individual sheets of printed text and a frontispiece illustrating the Buddha surrounded by acolytes and disciples. (Werner Forman/Corbis)

► THE PRINTING OF THE *DIAMOND SUTRA*

In 1907 Sir Aurel Stein (1862–1943), a Hungarian-born British explorer, bought around 7,000 scrolls of text that had just been discovered in a hidden chamber in the cave-temples in Dunhuang (now Gansu Province). Among the scrolls was the oldest surviving printed book, titled *Jin'gang banruo boluomi jing*, or *Diamond Sutra* (Sanskrit: *Vajracchedika Prajna Paramita*). This Buddhist sutra became known in the Chinese territories in the fourth century when the monk Kumarajiva (b. 344), a famous translator of Buddhist texts, translated it from Sanskrit into Chinese. It is a short sermon attributed to the Buddha in which he explains the illusionary nature of reality and urges listeners to see through the deception of names and concepts. According to the Buddha, the power of this teaching resembled that of a diamond cutting through even the hardest materials. The copy that Stein bought and then transferred to the British Museum (now the British Library, London) can be dated to circa 868 based on internal evidence. The scroll concludes with a

colophon in which the sponsor dedicated the printing of the sutra to his parents and dated the project to 868 CE.

The book consists of seven long printed sheets, each drawn from a different woodblock. The sheets were pasted together right to left, forming a scroll 17.5 feet in length. It opens with an illustration of the Buddha surrounded by devotees. The quality of the illustration as well as the printed text demonstrates the advanced skill that Chinese printers had already attained by the ninth century. The sponsor's hope, expressed in the colophon, that the printing of this sutra would result in positive karma for his parents illustrates the role of Buddhist beliefs and the Buddhist investment in the duplication of texts in the development of printing in the Chinese empire.

20 feet, survive. Around 770 the Japanese Empress Shotoku (r. 764–770) ordered 1 million copies printed of the same Buddhist charm. She had the copies stored in tiny wooden pagodas and distributed among ten Buddhist temples. Several printed copies are extant. Chinese archaeologists discovered similar printed Buddhist charms in tombs excavated near the Tang dynasty capital of Chang'an (present-day Xian) in 1967 and 1974–1975. These may predate the charms discovered in Korean and Japanese temples. By the ninth century, Chinese printers produced Buddhist texts, calendars, dictionaries, pedagogical texts, and titles on medicine and prognostication.

The invention of printing was not sudden or unexpected. Regardless of whether one sees printing as a Korean or a Chinese invention, there is no doubt that the development of printing was an extension of preexisting technologies first developed in the Chinese territories. The Chinese character for printing (yin) is the same as that used for a seal and the stamping of a seal. Seal carving is very similar to the carving of woodblocks. A mirror image of the image or

text to be reproduced was carved in relief on a flat and hard surface. Seals had been in use since around the twelfth century BCE. They were carved in stone, jade, ivory, horn, and wood or cast in bronze, gold, silver, and iron. Before the invention of paper, users of seals stamped them on clay or silk. From the fifth century CE onward, government officials and literate elites commonly applied red ink to their seals and stamped them on paper. Seals sometimes carried a short text. Daoist priests, for example, used seals in the centuries preceding the invention of woodblock printing to duplicate charms.

By the sixth century, artisans developed a method for applying paper to an inscribed surface to produce a copy of the inscription. This method, called rubbing, was used mostly to reproduce stone inscriptions. An artisan pressed paper onto a stone stele-carved intaglio and applied black ink to it, thus producing a black sheet with white characters (showing the carved-out areas).

The techniques of seal carving and producing rubbings, along with the Chinese invention of pa-

per around the second century BCE and the use of black ink from the first millennium BCE at the latest, were the preconditions for the development of printing. The dharani discovered in Korea was printed by the woodblock method. Woodblock printing became the dominant method in Chinese printing, even though movable type was used throughout the second millennium CE and other media such as copper plates were occasionally substituted for the woodblocks. Typically, the blocks were cut from the wood of deciduous trees such as pear, jujube, catalpa, boxwood, ginkgo, or the Chinese honey locust. They were rectangular in shape, with their size depending on the desired size of the book. The first step in the carving process was the transcription of the manuscript to be printed with brush and ink onto thin sheets of paper. Next, an artisan placed the calligrapher's wet transcript, face down, on the block so that a reverse image of the text was transferred onto the block. Then the carvers were put to work outlining the reversed characters with a cutting knife and removing all the wood not covered by ink with a chisel. The process was repeated for the opposite side of the block; blocks were frequently carved on both sides. Because the carvers were low-paid laborers and oftentimes illiterate, literate men proofread a trial print. The carvers made the necessary corrections to the block by excising mistaken characters and plugging in substitute pieces of wood with the corrected text.

After the final editing, the blocks were ready for printing. Printers placed the prepared blocks on tables and applied ink to the characters with an inking brush. While the ink was wet, the printers laid white or yellow sheets of paper on top of the block, covering its entire surface. They gently pressed the paper against the block with a rubbing pad and thus obtained a clean and positive copy of the carved text in black characters. The printing process could be repeated immediately to obtain any number of copies; the owners of the blocks could also keep them in storage to produce further copies at a later date.

At first, printers preserved the appearance of manuscript texts. Calligraphers designed the characters, and the printed sheets were pasted together to form scrolls just like manuscript

texts. The earliest extant complete book in print, the Diamond Sutra, was produced in this fashion. Gradually, the new technology of printing brought about changes in book formats. In the ninth and tenth centuries bookbinders used a binding style in codex format. They folded the printed leaves down the middle, piled the folded sheets on top of each other, and then pasted stiff paper alongside the center folds to hold the sheets together. Because in the minds of some readers the leaves resembled the wings of butterflies when opened, this binding style was called butterfly binding.

The fact that the earliest extant printed texts in Korea, China, and Japan and the earliest extant printed book are associated with Buddhism illustrates its significance in the early development of the medium of print in Chinese history. According to T. H. Barrett, printed texts were part of a wider set of objects whose multiplication generated merit or karma for the individual producing and distributing them. Religious texts were equivalent to relics whose presence embodied holiness and were thus not necessarily produced to be read or used for instructional purposes. Printing was a useful technology for Buddhists because it made the duplication of thousands and even hundreds of thousands of printed relics faster and more reliable than copying by hand.

During the ninth century private printers and booksellers also used print technology to distribute a small repertoire of practical texts. Most popular among those were privately printed calendars. Calendars indicated propitious and unlucky times for agricultural and other activities of daily life and thus regulated the lives of households and communities. Their circulation challenged the state's prerogative in ordering time and thus prompted Emperor Wenzong (r. 826–840) to issue an edict in 835 prohibiting the private printing of calendars. Other ninth-century printed texts (such as printed manuals on prognostication and medicine, dictionaries, and a guide for the moral education of girls) similarly appealed to a broad and not necessarily scholarly readership.

A major shift in the application of print technology occurred in the tenth century. From the early tenth century onward, government and

private printers began to produce and distribute scholarly literature in print. The most conspicuous project was the printing of the classics associated with the Confucian tradition, comprising 13 titles in all, between 932 and 953. Until this time the government had published standard editions of the classics by inscribing them on stone steles. The printing of the classics, led by Feng Tao (881–954), who served in high court positions in five dynasties, symbolized the state's awareness of the power of print and promoted its acceptance among the political elite. Later in the tenth century similar large-scale printing projects resulted in the printing of the Daoist and Buddhist canons. These developments prepared the stage for the expansion of both government and commercial publishing during the Song dynasty (960–1279).

Gunpowder

Gunpowder may be the most important discovery in world history. It changed the way in which wars were fought and substituted chemical energy for muscle energy in many activities. Ironically, gunpowder apparently owed its origin to the search by Daoist alchemists for an elixir for eternal life.

Early Daoist alchemists in China conducted many scientific experiments before the beginning of the Common Era. The centralized government of Emperor Wu Di (156–98 BCE) financed a systematic search for mixtures that could bring

everlasting life. Researchers identified a number of compounds and cataloged their uses. Sulfur and saltpeter were among these, and recipes dating from 2,000 years ago include both. By 950 CE, mixtures including charcoal had been developed. Alchemists often used fire or heat to treat their mixtures, sometimes with disastrous results. Many of the early written recipes, such as those by Wei Boyang in the *Book of the Kinship of the Three*, were intended as warnings to alchemists that some mixtures should not be made.

Protogunpowder developed by alchemists was recognized as being toxic and not a source of life. They quickly found other uses for *huoyao* ("fire drug"). It was used to treat skin sores and ringworm. Physicians also used it as a fumigant to kill insects and to dispel chills and fevers.

Huoyao burned rapidly with a great deal of smoke, but applying its explosive powers to military uses was not appreciated until the tenth century. By the second century CE, Chinese craftsmen had stuffed sections of bamboo with *huoyao* and plugged both ends. The bamboo was then thrown into a fire, where it exploded with noise and a flash. Later they added a fuse to the side, creating firecrackers. Fireworks makers soon recognized that plugging one end of the bamboo would allow flames and sparks to shoot out of the open end, resulting in what became known as Roman candles.

Many Chinese military leaders were followers of the Dao philosophy, and they apparently learned of the secrets of *huoyao*. By 950 CE a printed formula for gunpowder had appeared. At first, the ratios of sulfur, saltpeter, and charcoal were roughly equal, resulting in a very low-power explosive. Military leaders learned that increasing the amount of saltpeter would result in a more powerful explosive. The first military use was recorded in 904 CE when Chinese armies used incendiary projectiles called flying fires. They attached bamboo tubes filled with gunpowder to arrows, lit fuses, and fired them against opposing armies.

By the eleventh century, the Chinese military had developed different types of gunpowder weapons. The first was a gunpowder bomb thrown by a trebuchet that would hopefully explode among opposing soldiers. The second was a similar bomb with hooks. The intention was

that the bomb would stick to a building or other wooden structure and that the explosion would set it on fire. The third was a poison-smoke ball, which would emit clouds of poisonous smoke. For this purpose, arsenic or other poisons were mixed with the gunpowder. Some Chinese soldiers also used versions of Roman candles as crude flamethrowers.

Observers realized that gunpowder had propulsive power, and the first rockets were developed by the thirteenth century. They were inaccurate and had limited physical impact. The rockets' psychological impact was apparently greater. Other Chinese soldiers used tubes filled with gunpowder and bits of glass, metal, or rocks. When the gunpowder ignited, the pieces were blown out. These weapons may be considered forerunners of cannons. Ironically, the development of gunpowder weapons slowed in China, falling behind the Europeans, who imported the secret of gunpowder from the Chinese.

Porcelain and Ceramics

Ceramic technology reaches back to the New Stone Age. In its simplest form clay was molded or shaped, dried, and then fired in a wood fire to temperatures of 800–1,150 degrees centigrade, creating earthenware, a product that was still somewhat porous. Glazes were later developed to make it waterproof. In 600 CE ceramics were mostly of this type with the exception of China, where ceramic technology reached a high level of sophistication as early as the first millennium

BCE. In China, ceramics were divided into two groups: low-fired earthenware and high-fired wares, including both stoneware and porcelain. Stoneware was fired to 1,200–1,300 degrees centigrade, which created a hard waterproof product that emitted a ringing sound when struck. Between the sixth and the eighth centuries CE Chinese potters discovered how to manufacture porcelain. Composed of kaolin and other ingredients and fired to an even higher temperature (1,280–1,400 degrees centigrade), porcelain is waterproof, vitrified, and semitransparent. Its beauty made it a desired trade item throughout Eurasia and later the entire world.

China was able to create the world's most technically superior ceramic wares because of, in part, their development of efficient high-fire reduction kilns. They produced a wide variety of products from coarse utilitarian wares to sophisticated porcelains, but it was the high-end products that were traded to the West and that influenced the development of the ceramic industry there. White stoneware or porcelains glazed with a thin transparent greenish or bluish glaze called celadon were originally in high demand but declined in popularity with the development of the bright Tang three-colored lead-glazed wares called *sancai*. These glazes, applied over stoneware, dripped and flowed, creating fuzzy borders reminiscent of the Tang tie-dyed and resist-dyed fabrics. *Sancai* was used

➤ A CHINESE SECRET—PORCELAIN

In the ninth century an Arabic merchant named Suleyman describing trade in Canton, China, reported on an amazing new discovery. He wrote of “a clay of superior quality with which bowls are made which are as thick as glass bottles; liquid inside them can be seen through them.” He was describing porcelain, a Chinese invention that would eventually rival silk as the most coveted import from China. Suleyman also describes an exciting new beverage he sampled that would eventually help fuel Europe's desire for porcelain: tea. These two items would soon rival silk as the premier Chinese export.

—*Rebecca Wendelken*

on dishes and pottery but also on sculptural pieces that often depicted horses, camels, and foreign merchants from the Silk Roads as well as young women and dancers. Many of the sancai pieces were created for funerary ware to be used in China, but some was exported to Persia and Byzantium, where a lively trade in copies developed. In the ninth century celadon again became popular, perhaps coinciding with the adoption of tea drinking, but the majority of Tang production consisted of Yueh ware, a stoneware covered with a greenish or putty-colored glaze. The designs were often influenced by Persian and Byzantine metalwork and motifs including palm trees, cherubs, swags, and dancers. Pieces of this fine-grained stoneware have been found from Japan to the Near East and on the eastern coast of Africa, showing the widespread trade in Chinese ceramics. The fall of the Tang dynasty fragmented China politically, but the turmoil did not stop the production of pottery. It continued to be produced in large quantities for both domestic use and for export.

Production in Korea and Japan was based on Chinese technology. Korean ceramics, especially after Korea's unification in 688, developed rapidly under Tang influence. Koreans perfected the production of celadon wares in the eleventh century, and their work rivaled that of the Chinese. Japanese potters were slower to develop more advanced techniques. The fashion for anything Chinese, especially among the elite, meant that domestic production was mostly limited to utilitarian wares. Local potters attempting to copy Chinese sancai ware could not meet the high standards of the Chinese products until high-fire kilns were imported from Korea. This finally allowed the Japanese to make a hard, dark gray stoneware. These pots were distinctly Japanese and of a much higher quality but continued to be used mostly by commoners. Porcelain wares were not produced in Japan until the early seventeenth century.

European ceramics suffered after the fall of the western Roman empire, as more advanced techniques used by the Romans were eventually forgotten. Only in Byzantium did technical innovations such as the potter's wheel and lead glazing continue to be used. Byzantium devel-

oped a lively decorating technique that included scratched and incised patterns and was greatly influenced by the technical advances in the Arab world and the products of China.

As Islam spread throughout Asia and North Africa, ceramics in those regions flourished due in part to a prohibition found in the hadith against eating or drinking from vessels of precious metal. This led to a brilliant tradition of ceramics decorated with geometric and calligraphic designs. In Persian areas the decoration took the form of human and animal representations despite the Quranic prohibition. The Abbasids in Baghdad and the Fatimid dynasty in Egypt had especially outstanding works. Nishnapur in eastern Persia was known for its underglazed wares, while in other areas Islamic ceramics sported vivid green, blue, and turquoise glazes over incised patterns. Technically, Islamic regions developed an opaque tin glaze that gave a white surface for decoration. New techniques including applying enamels to the surfaces of glazed pieces and the use of metallic lusters to simulate metalwork were developed. Islamic pottery borrowed motifs and forms from China, which illustrates the cultural exchanges along the Eurasian trade routes.

Earthenware technology was known in Africa since early times, but to date few pieces have been recovered outside of Egypt and North Africa. One notable exception has been the discovery of a number of large helmet-shaped earthenware heads from the sixth or seventh century. Their original use has not been determined.

In the Americas ceramic production was limited to unglazed earthenware pieces, although shiny and more waterproof surfaces were achieved by burnishing the clay surface before the pieces were fired. Minerals such as ochre or iron oxide were sometimes used to decorate the surfaces either before or after firing. The Maya were especially adept at this technique, creating finely painted ceramics for religious and domestic use. Small-scale sculptural figures of people from all walks of life were rendered in realistic detail. By 1000 earthenware technology was known to most of the settled peoples of the Americas.

Silk

The technology of silk cultivation and production developed in China more than 6,000 years ago. Silk cloth and thread were major Chinese trade items even before the Han dynasty (206 BCE–220 CE). Bolts of silk cloth were used as a medium of exchange and formed a large part of tribute payments to hostile groups along China’s periphery. Because silk brought high profits, peoples outside China were eager to learn the secret. Some, such as the Japanese, were given gifts of silkworm eggs by the emperor of China. While China’s production was sufficient to allow even commoners to have some silk clothing, in Japan smaller production meant that the use of silk was restricted to the court.

If they could not receive the technology by gifts, others resorted to early industrial espionage. The West had a silk-weaving industry, but it was entirely dependent on imported Chinese thread. Sassanid Persian textiles were especially prized for their excellent techniques and unique patterns. However, the supply of silk thread along the Silk Roads was not always dependable. At times, silk cloth was taken apart and the threads rewoven in more marketable local patterns. The solution was to gain access to the technology of silkworm cultivation. According to legend, in 552 Nestorian monks hid Chinese silkworm eggs in their walking staffs and carried them back to Byzantium. Whether this story is true or not, by the seventh century China’s monopoly on silk thread

➤ NOT EVERYONE FAVORED SILK

With its high cost and connection with decadent life, silk cloth was not only coveted but also condemned. Silk, widely used for covering relics, for vestments, and for decorating places of worship, was forbidden as secular war by religious leaders of many faiths. The Quran said that the righteous would be clothed in green silk woven with gold in heaven, but those who wore it on earth would not be allowed to enter. In Christianity, St. Jerome issued similar admonitions against wearing certain luxurious clothing, but Hindus thought that silk was so pure that it was perfect for ritual use. It did not even need to be washed first.

—Rebecca Wendelken

production was broken. Silkworm cultivation centers and a silk thread industry were set up in Syria. Its weavers produced fabulous silk brocades treasured throughout Eurasia, but, like Japan, the West could not produce enough to meet all its needs. The West continued to import large quantities of Chinese silk to meet the growing demand.

During the ninth century the Byzantine silk industry thrived, and the government maintained a monopoly on its production. They produced their own designs but also borrowed motifs from Persia and China. From Byzantium, silk manufacture spread to Italy, again by illegal means. By the tenth century Venice and Amalfi were trading in locally produced illegal silks. As Byzantium’s power waned and turmoil in central Asia caused the Eurasian Silk Roads trade to decline, the Italian peninsula became the primary source of Western silk.

Another early producer of silk fabric was India. India received Chinese silk weaving technology in the Gupta period (400–600 CE) but like the West remained dependent on imported silk thread. Chinese silk was often mixed with native wild silk or cotton to produce spectacular cloth. India resisted silkworm production along Chinese lines because the process killed the pupa to keep the cocoon intact. This may have violated Hindu religious laws, and India continued to import Chinese threads.

As the secrets of silk cultivation spread, China developed many new techniques in silk weaving and dyeing. During the Tang dynasty (612–906), Han warp-patterned brocades were replaced by Western weft-patterned brocade techniques, and motifs moved away from linear Han designs to more overall patterns. Other Western weaving techniques including twill weaves, and new patterns were copied from Sassanid Persia and Byzantium. Foliate patterns, including the palmette and half-palmette, confronted animals, and the Sassanian pearl-edged medallion and royal hunting scenes, were adapted to Chinese tastes. New dyeing techniques such as wax and clamp resists and patterned tie-dyeing also developed, allowing even commoners access to decorated silk clothing. In the eighth century Chinese weavers moved toward more natural designs. In the following century woven textile designs became more

formal, although naturalistic motifs remained popular. By the Song dynasty the patterns and colors became more subtle, and Chinese weavers perfected the satin weave. Although it lost its monopoly, China retained its position as the premier silk producer, and Chinese silk and production technology continued to be avidly sought after in world markets.

■ Introduction: Travel Technology

Some very important innovations in travel technology were made during the Era of Expanding Regional Civilizations. Norsemen crossed the Atlantic, traveling west to North America, while Polynesians reached South America from the east, completing their exploration of the eastern Pacific Ocean. That they were able to do this was partly due to their steady innovation of marine technology. The Polynesians did it by constructing large double-hulled oceangoing canoes, which could survive storms and gales, as well as by mastering sailing techniques that allowed them to sail into the wind. On the other side of the globe, the Norsemen in the eighth century began building large oceangoing keeled longboats that allowed them to sail and row the hundreds of miles of open water between Norway (or Scotland) and Iceland, between Iceland and Greenland, and from Greenland to North America.

Probably even before the start of this era, Austronesian speakers from Indonesia began constructing sewn boats to sail, using lateen sails,

across the Indian Ocean to the east coast of Africa and then to Madagascar. These Austronesians may have given the Indians and the Romans the technique of crossing the Indian Ocean with the seasonal monsoon, and they may have imparted to the westerners the use of the lateen sail. Regardless of the way they learned it, the Indians, Romans, and Greeks and then the Arabs and Persians took advantage of the seasonal monsoons to cross the Indian Ocean throughout this period. Also, since the beginning of this era, the lateen sail was known in the Mediterranean, although it probably did not become common in the Mediterranean until about the sixth century. One of the most important innovations in marine navigation was the Chinese invention of the sternpost rudder, perhaps as early as the sixth century.

The use of the lateen sail spread to ships sailing up the Nile River in Egypt. The Nile has been a very busy highway, partly because of the interesting opposition of the prevailing wind and the river current. While the current flows uniformly north, the prevailing wind for much of the year

is upstream, to the south. Sailors on the Nile solved the problem caused by the shifting winds by developing the felucca, a type of river craft that uses lateen sails. River transportation and trade were important wherever there were navigable rivers, such as the Mississippi and Amazon systems. In those two rivers and in many others throughout the world, the dugout canoe was the most widely used river craft. In China, especially on the Yangtze, craft that could carry much larger loads were used. A problem concerning travel on the Yangtze was the powerful current, making travel upstream difficult and sometimes impossible. This problem was ameliorated somewhat by the construction of towpaths along the banks of the river. These towpaths were sometimes chiseled into the rock cliffs that enclosed the river as it rushed through gorges.

During this period, China constructed an elaborate system of inland water transportation using an elaborate combination of rivers, lakes, and canals. The Grand Canal was constructed during the Sui dynasty (589–617) to transport grain from the Yangtze Valley to the capital at Chang'an, which was the longest transport canal ever built.

China as well as other civilizations built roads for communication and transportation. In the Andes, the Wari empire built roads for its human bearers as well as for llama pack animals to travel. Radiating from Chaco Canyon, the inhabitants built a system of roads with communication towers to outlying supply areas. In India, to complement the Ganges River transportation, several dynasties constructed the Grand Trunk highway for express riders and bullock carts from Patlipatra in Bihar to Peshawar, now in Pakistan.

The Romans built one of antiquity's most extensive and durable road systems to move armies across their empire. After the fall of the western Roman empire, the road system there was allowed to fall into desuetude, and the Arab conquerors abandoned the Roman roads in the Roman provinces they conquered. The Arabs had a faster and less expensive transportation technology than the bullock cart previously used. Everywhere the Arabs went, they brought the dromedary camel, which could carry loads of up to 300 pounds and travel through territories without roads. With the spread of the Arab

Muslim empire in the seventh century, transportation and travel became not only less expensive but also more extensive. Travel across the Sahara Desert by camel caravan made cross-desert trade and travel at least an annual occurrence.

The rise of the Muslim caliphate and the Tang dynasty stimulated the transhemispheric trade on the Silk Roads. For this a special hybrid camel was developed, a cross between the Arabian dromedary and the central Asian Bactrian camels, with the strength and endurance of both.

China's Inland Waterway System of Transportation

China has an immense inland waterway system that incorporates 5,600 navigable rivers with a total length of roughly 73,800 miles (119,000 kilometers) as well as a vast network of canals. The majority of China's total length of navigable waterways can be found within the courses of the Yangzi, Pearl, Huaihe, and Heilongjiang rivers. The Yellow River (Huanghe), one of the major rivers of China, is not easily navigated. The Yangzi, together with its tributaries, has a navigable length of approximately 36,000 miles (58,000 kilometers).

China has a vast network of canals, some of which date as far back as the latter years of the Zhou dynasty (ca. 1100–256 BCE). Many of the canals were built in a north-south direction to connect the Yangzi, Yellow, and other rivers, which run from west to east. One of the more ambitious of these canals, the Hong Guo, constructed perhaps as early as the sixth century BCE, connected the Yellow River near Kaifeng to the Si and Bian rivers. The Qin dynasty built an irrigation and transport canal in the Wei Valley that greatly increased the productivity and population of the area. The emperor Han Wudi (r. 141–87 BCE) built a canal connecting the Han capital city of Chang'an (present-day Xi'an) to the Yellow River.

The next burst of canal building occurred during the Sui dynasty (581–618) with the commencement of what was to become the Grand Canal. The canal became necessary due to the migration of China's core economic and agricultural region away from the Yellow River valley

THE GRAND CANAL OF CHINA

China's Grand Canal, which is about 1,200 miles (1,764 kilometers) in length, is the world's longest man-made waterway, linking China's major rivers with many of its major cities. The canals were built to facilitate the flow of food and commercial and military goods quickly from the south to the north.

The construction of the main elements came during the reign of Yang Guang, the second emperor of the Sui dynasty (581–618). The canal extended from Hangzhou northward across the Yangtze River to Yangzhou and then northwest to the region of Luoyang. After 609 the canal was extended northeast to the region of Tianjin and Beijing. This first canal joined up a network of older existing waterways so that barges could travel from the Yangtze to the Yellow River and then on up the Wei to the western capital at Xian. It is estimated that as many as half of the six million workers assembled to build the canal died from exhaustion and/or hunger.

During the Yuan dynasty (1271–1368), the Mongols moved the capital of China to Beijing, thus eliminating the need for the old canal flowing west to Kaifeng or Luoyang. The Mongols built a new canal from Hangzhou directly north across the Shandong massif during the 1280s north to Beijing. A sophisticated system of locks facilitated travel along the canal.

Today the Grand Canal is only navigable in certain sections and functions more as a symbol of past glory rather than as an important economic resource.

—Daniel A. Métraux

in the direction of the area now consisting of Jiangsu and Zhejiang provinces. Its purpose was to facilitate the transport of grain to the capital. With rapid population growth in the Yangzi River valley, many canals had been built to transport grain from the south to the north, but before the Sui period they were not linked together into one network. The Sui reopened the old Han-era canal between Chang'an and the Yellow River in 584.

Within the next decade the Sui had built an ambitious canal between the Yellow River and the Huai and on south to the Yangzi at Yangzhou. By 608 the Sui had completed a canal from

the Yellow River to what is today Beijing in order to better supply Sui armies in their ultimately unsuccessful invasions of Korea. Two years later the Sui extended the canal southward from Yangzhou to the rich rice lands of the Yangzi Delta to the river-port city of Hangzhou. This new network of canals became known as the first Grand Canal. It should be recognized that the Grand Canal at this time was not a continuous man-made canal but rather a collection of often noncontiguous artificial cuts and canalized or natural rivers.

The opening of the Grand Canal connected the basins of the Yellow and Yangzi rivers, thus linking the two major population centers of the country and spurring a critical growth in domestic and, by extension, foreign commerce. The Grand Canal itself was further supplemented by ancillary routes that carried goods to the northwest. With the intense labor of as many as five million men and women under the supervision of Ma Shumou, the first major section of the Grand Canal, called the Bian Qu, was completed by 605. The Grand Canal was fully completed under the reign of the second Sui emperor between 604 and 609 by first linking Luoyang to the Yangzhou (and the Yangzi Valley) and then by expanding south to Hangzhou and north to the area now encompassed by Beijing. Its total length was approximately 1,560 miles. This construction allowed southern areas of China to the northern provinces of China as well as to troops in the north. An imperial roadway was constructed along the canals along with post offices connected by a courier system.

During the Tang dynasty (618–907) the city of Yangzhou near the Grand Canal became the economic hub of China. The city itself was crisscrossed with canals, many built during the Tang period, and, it is said, had more boats than carriages. Yangzhou was the geographical midpoint of the canal and became the major locale for southern goods shipped to the north. A few modifications and additions were made in the canal to cut down travel time, but there was little major canal building during the Tang dynasty. An important innovation of the Tang period, however, was the construction of locks at various junctures along the canal to better facilitate the transport of specially constructed river

barges as well as the flow of the water. By the year 735 it is estimated that as many as 165,000 tons of grain were shipped along the canal.

Roads in the Chaco Canyon State

Archaeologists were amazed during the twentieth century when they discovered the existence of roads around Chaco Canyon in modern New Mexico that were built by the Anasazi Indians 1,000 years before. Speculation followed about the purpose of the roads. The Anasazi had no wheeled vehicles and no pack animals, so archaeologists were mystified as to why they would exert such effort on building roads.

The roads were constructed between 900 and 1100 CE. Most range from 26 to 32 feet (8 to 10 meters) wide, although some are as narrow as 6.5 feet (2 meters). The ones located near major archaeological sites usually are wider, while the segments located in more distant areas are much narrower. The roads were made by excavating and smoothing out the earth. Only a few stretches were excavated to bedrock or had hard tamped soil as a foundation. Most often, the roads followed the contour of the land. In a few cases, high and low areas were leveled. More often than not, ramps or stairways were constructed over difficult terrain. Time and weather have caused damage to many of the road segments as well.

One distinguishing feature about the roads built by the Chaco Canyon dwellers is that the edges of the roads were delineated. Along some stretches, simple rocks were placed periodically along the edge. In other places, rock walls were constructed. In still other parts, an earth curb or a berm was built up. Other constructions have been found near the roads, including rock enclosures and multiroomed buildings known as *zambullida*.

At first, archaeologists assumed that the roads were constructed for economic reasons, to assist trade and communications. The roads appeared to begin in the Chaco Canyon and have been found throughout the San Juan Basin. Some may have been used to transport water from springs to communities. Other roads may have been used to help redistribute food supplies between different communities. A difficulty with this explanation is that many of the roads have gaps or exist as isolated segments. Some segments actually parallel others, with a few hundred meters between them. Although the destruction of some roads since their construction makes it difficult to be certain, the widespread road network does not seem to connect. The north and south roads extend over 40 miles in nearly straight lines, but they do not appear to go to specific destinations.

A religious or political explanation for the roads' existence has been suggested. Many of the roads are associated with great houses or great kivas that were in use by the Anasazis during this time period. Although few details about the Anasazi religious beliefs are known, both structures played a role in their rituals. The roads may have played a symbolic role.

Another explanation is that the roads had a political aspect. Much as the pyramids, they may have been built by local leaders to enhance their prestige or to help tie their communities of people together.

Boats and Ships of the Mediterranean

During the first millennium CE, vessels that sailed the Mediterranean changed considerably in their appearance from their predecessors of the Greco-Roman period. The overall sizes, types, and methods of construction and propulsion of ships were modified significantly, indicating an advancement of shipbuilding technology. These developments also indirectly reflected the reactions to the various political and economic situations that were emerging in the Mediterranean during this period.

Between the fourth and sixth centuries CE the Roman political and economic dominance that once unified the Mediterranean was fragmenting. New polities from central Europe had reached Italy, Iberia, and North Africa, seriously reducing the empire in size and altering what remained of its western maritime-based commerce and communication routes. The large merchant vessels with several sails once indicative of imperial economic stability and state-controlled commerce were no longer viable. Foreign shores, wider-spread piracy, a lack of broad governmental controls, and changing populations in the west created an environment more conducive to smaller ships. Roman-era cargo vessels of more than 131 feet in length and capacities of more than 400 metric tons gave way to smaller merchant ships that carried a single sail and averaged 49–65 feet in length with a capacity of 40–50 tons. These vessels had fuller hulls that helped maximize the quantity of cargo they could carry.

Galleys, the long and narrow warships that were propelled mainly by oars, also underwent modification. The Roman imperial galleys had possessed more than one row of oars to a side and a heavy bronze ram at their bow; the Byzantine galley (*dromon*) first emerged in the fifth century as a light, fast ship with a single row of oars, a single sail, and a small beak used by soldiers for boarding other ships. Beginning in the

seventh century, nearly identical galleys (sing. *shini*, pl. *shawani*) were also built for the emerging Arab navies in the Levant that readily utilized the maritime skills of native Byzantine shipwrights. The ninth and tenth centuries saw the simultaneous development within the Byzantine and Arab fleets of larger, heavier galleys with two rows of oars, several sails, and experimentation with flaming projectiles.

Ship construction methods also underwent extensive transformation. Typically, a Greco-Roman vessel had been built as a hull with a strong shell of planks that were joined at their edges by closely spaced pegged mortise and tenon joints (a rectangular flat piece of wood, or tenon, set into slots, or mortises, carved in each plank edge and held in place by a wooden peg driven through the plank and tenon). Frames were later added to the interior and attached with wooden dowels to the planks. In the third and fourth centuries CE, mortise and tenon joints had become smaller and more widely spaced along plank edges and lacked pegs to hold them. Gradually, by the end of the first millennium CE, the joints had disappeared, and boats were instead built with closely spaced frames that dictated the shape of the hull and provided its major support. Planks were then nailed to the frames with small iron nails. Ships constructed in this manner used less labor-intensive methods and wood, and the overall building costs were reduced.

The changed political and economic situation of the fourth and fifth centuries caused a reduction in the size of cargo ships sailing the Mediterranean. Smaller vessels with a single sail were easier to maintain and well suited for use by the increasing number of independent merchants who traded within the boundaries of the early Byzantine world or with foreign polities in the south, east, and west. In turn, the lighter galleys were a response to the need for rapidly deployable and maneuverable naval fleets for defense against a myriad of states that occupied the shores of the Mediterranean. These changes were made possible by the development of more economical ship construction methods that remained standard in the Mediterranean world until the nineteenth century.

—Athena Trakadas

THE ADOPTION OF THE LATEEN SAIL

Throughout the Mediterranean, square-shaped sails had been employed on ships to harness the wind since the Bronze Age. During the first millennium CE, however, triangular-shaped lateen sails were slowly adopted by mariners. The ability to set a lateen parallel to a ship's keel improves navigation over a square sail by enabling a vessel to maneuver more easily toward oncoming winds.

The development of the lateen was likely born out of experimentation with the square sail rig. The square sail's brails (ropes) were manipulated to form a triangle or inclined square sail in order to better sail into the wind. This manipulation evolved into the development of a triangular-shaped sail with more adjustable yard.

Artistic depictions in the Mediterranean show that sails different from square rigs appeared early in the first century BCE; by the fifth and sixth centuries CE lateens appear commonly alongside square sails and are described in texts. By the ninth century the square sail had lost favor to the newer rig, and by the twelfth century seagoing Mediterranean ships used only the lateen sail.

Lateen sails were also used by mariners in the Indian Ocean. However, the evidence of the origins of this sail type is not as extensive for this region. The first texts that mention sails, which are probably lateen, appear in the ninth century CE, and artistic depictions of lateens appear in this region in the tenth century. It is likely that the lateen developed in an independent yet parallel process in the Indian Ocean, following the same technical experimentation suggested for the Mediterranean. Some scholars argue, however, that the sail type was invented in the Indian Ocean and introduced

Ship with lateen sails introduced into the Mediterranean by Indian Ocean mariners about 500 CE. (Pearson Scott Foresman)

to the Mediterranean due to contacts between Greco-Roman vessels in the Red Sea and voyaging to India and Indian Ocean vessels in the first several centuries CE.

The Viking Longboat

The longboat was the primary vehicle of Viking discovery, communication, trade, and power, as Scandinavians of the Viking Age lived mostly by the sea or lakes. Made by iron riveting overlapping

The Oseberg ship on display at the Oseberg Ship Museum in Oslo. The Viking longboat lay preserved in clay for more than 1,000 years before its discovery in 1904 by Norwegian farmer Knut Rom. (Sunil Bhawe)

planks and being lighter and more agile than contemporary vessels of their size, the longboat found its classical design probably in the late eighth century. The largest found by archaeologists is 98 feet (30 meters) long and is the biggest of the so-called Skuldelev ships excavated outside Copenhagen in 1962. It was probably built in Ireland in 1042 and was deliberately sunk in order to block access to the Roskilde fjord for Norwegian invaders in 1070. Today it is on display in the Roskilde Viking Ship Museum, Denmark. The vessel was propelled by 30 pairs of oars and could carry about 100 warriors. However, according to Snorre Sturlason's sagas of the Norse Kings, Norwegian king Olaf Trygvason's flagship, the *Ormen Lange*, was between 131 and 164 feet (40 and 50 meters) long.

Construction varied according to purpose. For longer sea journeys ships used a single square

sail, while in shallow water or in battle they relied on oars for which also sleeker ships were specially built. When coming upon impassable streams or enemy coastal defenses, the crews could bypass the obstacles by rolling their ships on logs over land. This technique was used to travel through Russia from the Baltic to the Black Sea and when Vikings sacked Constantinople in 860 CE. During the Late Viking Age, broader ships were developed for transatlantic voyages and bulk transport.

In pre-Christian times, Scandinavian nobility were often buried in ships, suggesting their cultural and religious status. The well preserved Gokstad ship and Oseberg ship were both found in burial mounds from the ninth century. The former was excavated in 1880 and is 78 feet (23.8 meters) long and contained the remains of a man 7 feet (1.85 meters) tall who was 50–70 years old along with three minor ships, a tent, a sledge, and horse harnesses. Grave robbers probably removed other burial goods. The Oseberg ship was 70.5 feet (21.5 meters) long and contained the remains of two women, one thought to be a queen or a priestess, the other a maid. Burial goods still remained within the ship, including carpets and other decorative textiles. The ships are currently on display in the Viking-ship Museum in Oslo, Norway.

Polynesian Navigation

Prehistoric seafaring in the Pacific is the eastern part of Austronesian migration. Austronesian-speaking seafarers also sailed west and reached Madagascar off the coast of East Africa. The distance between that island and Southeast Asia is about 4,700 nautical miles (7,500 kilometers). Placing the Austronesian migrants' western and

eastern explorations in perspective, one may perceive the true magnitude of their global endeavor.

For an understanding of the intentionality of the colonization movement in the Pacific region it is important to understand how Polynesians have looked and still look at the world. This means that outsiders—whether Americans, Europeans, or people from Australia, Asia, or Africa—have to take into consideration the perception of Oceania in the cultural memory of the islanders. A modern observer who looks at a map of the Pacific region is impressed by the huge masses of water. This sort of vastness may evoke negative emotional associations such as emptiness of uncontrollable space, perils at sea, untraversable distances, vicissitudes of weather conditions, and the like.

The Polynesian mind-set, however, is differently tuned. An islander perceives the wholeness of Oceania in proportions different from that of outsiders. The many islands, scattered throughout the region, gain in profile as landmarks in a cultural landscape. The waters of the ocean are not perceived as unpredictable or even hostile. Instead, the ocean takes the role of a pathway connecting islands and communities rather than functioning as a boundary to separate them. The vastness of the Pacific Ocean forms part of the islanders' cultural space, a space for interaction between nature and human beings. This mind-set can be reconstructed from early maps that local guides drew for European sailors in the early days of contact. In these maps the masses of water are drastically reduced, whereas the islands are given emphasis as spaces for human agency.

The first migration into Polynesia from the west can be dated to circa 1500–1000 BCE. The migration of Austronesian people into Polynesia from Melanesia began in the second millennium BCE. The Fidji (Fiji) Islands are located in the central part of the area that was colonized during that early period. The Melanesian cultural complex, centered on Fidji, provides the foundation for the subsequently developing Polynesian culture that proliferates into a wide array of local cultures during later migrations. The proliferation of cultures finds its parallel in the direction of gene flow. The Polynesian lineages stem genetically from the gene pool of populations in western Melanesia.

A subsequent migration (ca. 200 BCE) within Polynesia that started from the Fidji group takes seafarers to the east. The settlements on the Society Islands, with Tahiti as their cultural center, date to the time of this migration. In circa 300 CE, a third migration began to eastern Polynesia. In this wave of migrations, the greatest distances in the Pacific Ocean were traversed by migrants from Tahiti. The far-out Easter Island is settled in the early fourth century CE. The sea route to the north of Tahiti also brings settlers to the Hawaiian Islands.

The last migration period (in the tenth century) sees the exploration of the sea route to the southwest of Tahiti, and migrants reach the islands of New Zealand in this period. The last of the bigger islands to be settled is the Chatham group east of New Zealand. The first Polynesians to reach Chatham around 1000 CE most probably arrived there not from New Zealand but instead on an independent voyage from Tahiti. The Moriori culture of Chatham declined in the first half of the twentieth century.

The time frame for the more recent migrations are conservative estimates. The more calibrated radiocarbon dates become available, the more accurate the association with the absolute timescale will be. It has been conjectured that early settlers may have reached the Marquesas Islands in far eastern Polynesia already at the beginning of the Common Era, several hundred years earlier than according to the conservative time frame.

In time, these seafaring endeavors became more frequent and better organized. This was due not only to farsighted planning of voyages but also to the accumulation of knowledge about climatic conditions and to technological advances. Each wave of migrants could profit from the experiences of previous generations to improve their know-how of seafaring. Many of the sea routes that had been explored in the course of colonization were already regularly frequented for trading more than 2,000 years ago.

The migrants who set out on their voyages in a west-east direction through Polynesia were agriculturalists and transferred the knowledge of food production (as horticulture and full-scale agriculture, where this was possible) to newly explored islands. In order to establish

► REENACTING PREHISTORIC POLYNESIAN SEAFARING

In modern times, seafaring with traditional vessels in the Pacific has been reenacted. The first to engage in such endeavors was the Frenchman Eric De Bisschop in the 1930s. De Bisschop's first voyage in a Chinese junk took him from Taiwan to Australia. Another more spectacular voyage was done shortly before the outbreak of World War II, this time from Hawaii to the French territory of the Society Islands in a Polynesian double-hulled vessel. De Bisschop's intention was to demonstrate that seafaring within Polynesia's vast expanse was possible in prehistoric times. The famed Kon-Tiki expedition that Thor Heyerdahl undertook with his crew in 1947 in an east-west direction (that is, from South America to the Tuamotu archipelago) presented a new challenge to De Bisschop, who set out in 1956 to navigate a route from west to east (from Tahiti to South America) in a bamboo raft with the name Tahiti Nui ("Great Tahiti").

Archaeological proof for long-distance trade relations between Hawaii and Tahiti left experts

skeptical as to how navigation over a distance of about 3,000 nautical miles (4,800 kilometers) between the two island groups is possible without modern nautical equipment. The Tuamotu group of islands (to the northeast of Tahiti) offered a special variety of basalt for making adzes. Since Tuamotu lies on the sea route from Hawaii to Tahiti, it is not surprising that adzes made from Tuamotu basalt are found both in Hawaii and in Tahiti.

A modern reconstruction of the Hawaiian two-sailed canoe, called *hokule'a* in the Hawaiian language, was used in 1976 to make a voyage from Maui in the Hawaiian Islands to Tahiti. This voyage was made without the help of modern instruments of navigation, with star configurations and the observation of currents and winds as the only means of orientation. The voyage was successful and may serve as a demonstration illustrating the possibilities of seafaring over long distances in prehistoric times.

—Harald Haarmann

new settlements at a distance from the existing ones, it was necessary to transport plants and livestock (i.e., pigs, fowls, and dogs). To safeguard the continuity of new settlements over generations, the migrant groups had to include both men and women.

It has been demonstrated by means of computer simulations of the migratory movements in space and time that the peopling of the Pacific islands cannot have occurred as the result of accidental drifts. Such accidental drifts would have produced random patterns, with densely populated islands contrasting with widely unpopulated areas. The only explanation for the regularities and the emergence of the dense web of local settlements is that the migrations were carefully planned. Polynesian demography is the outcome of intentional seafaring.

The Polynesians did not have any technical devices to facilitate their navigation, and they did not possess systems of notation to draw charts of currents or star configurations. What they definitely instrumentalized for their orientation at sea was their refined perception of nat-

ural phenomena. Over time a vast amount of specialized knowledge about seafaring accumulated, and this knowledge was transferred by means of oral accounts and memory from master to disciple in the professional domains of specialized handicrafts. The builders of canoes and catamarans would profit from the experiences of seafarers to make their vessels apt for maneuvering against high waves and gusty winds. And the settlers who took livestock and provisions on their journeys would learn from the stories that earlier migrants told to make improvements for their selection.

Arab, Shirazi, and Indian Ocean Navigation

During the first centuries CE, Indian Ocean navigation was dominated by Shirazi (Persian Gulf) and Axumite (present-day Ethiopia) mariners. Goods brought to Sri Lanka by Far East traders would be transported by Axumite ships to the Red Sea, Arabian Peninsula, and East Africa and by the Shirazi to the Persian Gulf. By the sixth century, western Indian ships had entered coastal trade around the Arabian Sea, but Shirazi vessels now dominated the former Axumite regions.

With the rise of the Arab Abbasid caliphate in Baghdad (ca. 750–1250 CE), Persian Gulf ports thrived under the demand for exotic goods. By the ninth and tenth centuries, Arab and to some extent Indian vessels controlled the western Indian Ocean trade routes and even sailed to China.

Knowledge of Indian Ocean seafaring during 300–1000 CE derives largely from a few navigational treatises and pictures, making it difficult to determine if there was great variation in the region's vessels. Unlike the ships of the Mediterranean, the edge-joined planks of the Indian Ocean vessels had seams sewn together by cords of coir (coconut) or palm fiber. The seams were filled with organic material for water tightness, and frames were fitted to the hull with cords as well. This nail-less construction method is documented

► THE BELITUNG SHIPWRECK

In 1997 a shipwreck was excavated off Belitung Island in the Indonesia archipelago between Sumatra and Borneo. The wreck had edge-joined planks sewn together with cords and seams filled with organic wadding. Frames were also attached to the hull by cords, and through-beams were set at the bow and stern. The nearly identical vessel ends were straight and pointed. Reconstructed, the ship was approximately 65–72 feet (20–22 meters) long, approximately 26 feet (8 meters) wide at amidships, and approximately 11 feet (3.5 meters) in depth. A cargo of lead ingots, a variety of Chinese Tang dynasty ceramics, and aromatic resins were recovered. A date equivalent to 826 CE inscribed on one of the ceramics provides the approximate period of the ship's sinking, confirmed by carbon analysis of the hull's timbers.

The vessel's appearance and construction methods are similar to ships described and depicted in contemporary Arab and Indian texts and pictures. Additionally, the woods used in its construction are native to the northwestern Indian Ocean. The wreck was likely an Arabian or Indian merchantman who perhaps sailed with a mixed crew that included Southeast Asians. Although it is possible that the ship had loaded its cargo in an Indonesian port, the uniform load suggests that it had sailed directly from a southern Chinese port and sank during its return voyage to the Arabian Sea region.

Chinese ceramics discovered in the Belitung shipwreck, dating from the Tang dynasty, ninth century CE. (Michael Flecker)

Archaeological finds at coastal sites in the Indian Ocean reveal that Chinese goods had been imported since the late seventh century; by the ninth century, texts state that regular Arabian and Indian voyages to China occurred. The Belitung wreck is the first archaeological evidence that Arabs or Indians traded directly with China during this period and also serves as the only known find of an Indian Ocean seagoing vessel of the first millennium.

—Athena Trakadas

in Roman, Byzantine, and Arabic texts from the first to fifteenth centuries CE and may have been the only method used in the region.

Teak and coconut, wood native to the region, were used to make durable, double-ended hulls. Through-beams near the railing at the ends added longitudinal strength and supported deck cabins. The wood types and sewn construction made it possible to build large flexible ships (approximately 200 tons) that endured hard seas and beaching along coasts lacking natural harbors. The ships were steered by two side rudders set near the stern. Although not mentioned specifically until the ninth century, a large lateen sail made of fiber or cotton was likely used; larger vessels perhaps had a smaller additional lateen.

Several Arab treatises describe regional sailing routes utilized by the mid-ninth century. Voyages could follow the coast, such as along the western shores of the Indian peninsula or along southern Arabia and to East Africa as far as Mozambique and Madagascar. Ships did cross open water, however, and could sail directly between the Persian Gulf and Zanzibar or the Horn of Africa to southern India and across the Bay of Bengal.

The open-water crossings were possible because of the harnessing of regular monsoon winds and the advent of celestial navigation. By the tenth century, primitive astrolabes could measure stars' orbits to determine latitude. Mariners also used shoreline charts, sounding devices (to observe sea-bottom composition), and

methods to read currents and identify seabirds to fix position.

The Arab dominance of maritime trade in the Indian Ocean reached its zenith in the ninth and tenth centuries; there is little information on seafaring again until the fourteenth century. Navigation certainly continued, particularly between the Red Sea and India, as Cairo became an economic and political center under the Fatimid caliphate. Arab writers noted, however, that no Arab ships ventured anymore to the Far East. European powers ultimately affected the remains of the once-prosperous maritime network. Portuguese mariners in the late fifteenth century discovered the regional navigation methods and trading ports. Soon after, French, Dutch, and British vessels also dominated the sea, competing for the valuable goods of the Indian Ocean.

■ Introduction: Early Medieval Medicine, Science, and Alchemy

When Byzantine emperors ordered the medical and scientific schools at Edessa and Athens closed, doctors who practiced medical science as taught by the great Greek and Roman physicians Hippocrates and Galen fled to Persia where, with the patronage of the Persian emperor Kusraw I, they joined the faculty of Gondeshapur, a teaching hospital and university. Although medical science atrophied in the Christian West after the fifth century,

Gondeshapur preserved the medical tradition of the classical Mediterranean world.

After the Muslim conquest, the Muslim authorities supported Gondeshapur and staffed the House of Wisdom (Baytu l-Hikma), a scientific library and research institute founded in Baghdad (832) where classical Greek and Roman medicine, together with Indian Ayurveda, was studied with graduates from Gondeshapur. This led to the emergence of Arabic medicine.

Ayurveda was and is a highly developed medical system that greatly influenced the development of Chinese, Arabic, and European medicine until the nineteenth century. The basic texts of Ayurveda, the *Susbruta Samhita* and the *Charaka Samhita*, were probably written in the last centuries BCE, and they were available in major Muslim cities in Arabic in the eighth century CE. They were widely used from Baghdad to Spain, and they were translated into Latin, probably by the twelfth century.

The *Susbruta Samhita* is a manual for maintaining health and preventing disease. Its focus is on diet and certain types of exercise, particularly breathing and yogic exercises. The *Susbruta* advises self-restraint in eating, sexual activity, and medication. Cleanliness, bathing, brushing teeth, cleaning the eyes, and use of ointments are advised. The *Susbruta* also stresses the use of herbal medicine and different types of massage as part of its health maintenance regimen.

The *Charaka Samhita* discusses more intrusive procedures, such as setting broken limbs, removing cataracts from the eyes, removing hemorrhoids, plastic surgery on the nose, caesarian births, amputations, and other surgical procedures. The Indians produced a wide assortment of surgical implements, which their mastery of the art of making the world's finest steel that could take extremely sharp and durable cutting edges made possible.

It is speculated that the development of medical science in India began in the Buddhist community because of the abhorrence of bodily fluids, blood, and dead bodies by many orthodox Hindus. Since contact with these substances led to ritual impurity, medical careers were closed to higher-caste Hindus but not to Buddhists and followers of some other heterodoxies. According to fourth-century Chinese visitors to Indian Buddhist sites, public clinics were established in some Indian cities, perhaps in the great Buddhist monasteries. The *Charaka Samhita* has passages describing the layout and equipment of such clinics.

Ayurveda traveled with Buddhist missionaries to China, where it influenced traditional Chinese medicine practiced by Chinese Buddhists. But Ayurveda did not have as deep an influence

on Chinese medicine as it did on Arab and, later, European medicine. Chinese medicine was a very highly developed science that, in the end, proved resistant to Ayurvedic influence.

Ayurvedic medical science may have been practiced mainly in the cities, the villages where at least nine-tenths of the Indian population probably depended on a variety of traditional curers for their medical care. Common forms of healing activities were pilgrimages to holy shrines; prayers, enchantments, and exorcism by sorcerers; and the laying on of hands by those thought to be especially holy.

In Europe, especially in the West, medicine as a science was unknown after the fifth century. Even West European rulers seldom had the attentions of a medical doctor trained in the classical tradition. Medicine in the early medieval West was regarded as akin to magic, and the cure of disease was seen as a religious rather than a scientific problem. It was not until toward the end of this era (300–1000) that the Europeans became aware of Arabic medicine.

Alchemy developed from work that closely paralleled that of medicine. In Eurasia, there were three major alchemical traditions: Chinese, Indian, and Arabic/European. While Chinese alchemy developed quite independently of the other two, Indian and Arabic/European were more closely related and had grown out of a common heritage of Hellenistic, Persian, and Indian traditions.

—Wilfred J. Bisson

Early Medieval Chinese Medicine

Medical practitioners of China's medieval period, conventionally 300–1000 CE, which spans from the Wei, Jin, Southern, and Northern dynasties to the early Song dynasty, made important innovations in medical practice. Physicians and intellectuals created medical knowledge and annotated classics, Daoists sought longevity, and Buddhist monks provided medical service in the Buddhist temples.

Inheriting the achievements of the Han dynasties, medical practitioners of this period contributed important innovations to the history of medicine. This can be observed in terms of both quality and quantity. Following the work of Hua

► EQUALITY IN MEDIEVAL CHINESE MEDICINE

Sun Simiao of the Tang dynasty, often revered as the “King of Pharmaceuticals,” had written two important medical books in Chinese history, *Beiji qianjin yaofang* and *Supplement to Beiji qianjin yaofang*. The two books almost included all medical arts of this period such as acupuncture, herbal remedies, dietary restrains, sexual arts, physical exercise, apotropaics, etc., to be like an encyclopedia of medicine. He also emphasized the importance of medical ethics and said, “If patients come and ask for help, a physician should disregard whether the patients are of high or low social position, rich or poor, old or young, pretty or ugly, enemies or friends, Chinese or foreigners, and stupid or wise. They should be treated equally and seen as the physician’s close relatives.”

—Ka Wai Fan

Tuo (most famous for his expertise in surgery) and Zhang Hongjing (the author of *Shang ban lun*) at the end of the Eastern Han, prominent physicians such as Ge Hong, Wang Shuhe, Huangfu Mi, Chen Yanzhi, and Tao Hongjing emerged in the Wei, Jin, Southern, and Northern dynasties. They wrote medical classics that greatly influenced the succeeding generations. *Mo jing* (*The Pulse Canon*) by Wang Shuhe and *Zhenjiu jiaiyi jing* (*The Classic ABCs of Acupuncture and Moxibustion*) by Huangfu Mi continued to be consulted for many centuries. In terms of quantity, according to *Suishu jingji zhi* (*The Bibliographic Treatise from the History of the Sui*), 256 medical treatises were written in this period. Their topics cover a number of subjects: explanation and interpretation of classics, materia medica, medical formulae, diet, breathing conduction, alchemy, the art of sex, and *qigong*.

The number of medical works reflects a diverse range of topics and approaches. We can assess this from three perspectives. First, medical books such as *Suwen* (*Plain Questions*) and *Ling shu* (*The Vital Axis*), both extracted from *Huangdi neijing* (*The Inner Classic of the Yellow Emperor*), and *Huangdi jiaiyi jing* (*The Classic ABCs of the Yellow Emperor*) appeared in various versions. Second, during the Wei, Jin,

Southern, and Northern dynasties, experts in materia medica turned to *Shennong bencao jing* (*Shennong’s Classic on Materia Medica*) as the most fundamental and authoritative work on the subject. Many studies of materia medica appeared, with illustrations and discussions of how to cultivate and prepare herbal remedies. Physicians drew up their own versions of materia medica knowledge informed by their personal experiences. For example, Wu Pu, a student of the famous Han physician Hua Tuo, drew up a quite idiosyncratic *bencao* (materia medica). Third, after the discovery of large numbers of acupuncture points during the Han dynasties, the seminal work on the subject, *Huangdi Mingtang jing* (*The Bright Hall Classic of the Yellow Emperor*), appeared in several different versions. *Suishu jingjizhi* records works on acupuncture written by Bian Que, Hua Tuo, Qin Chengzu, Long Xiansu, the monk Sengkuang, and many others. Although many of these have been lost, passages from a good number were quoted in *Ishinpō* (*A Guide to the Heart of Medicine*) written by Japanese doctor Tanba Yasuyori in 984, which shows clearly that the methods and the very points used by acupuncturists had varied a great deal.

In the 300 years between the end of the third century and the end of the sixth century, two groups took it upon themselves to transmit medical knowledge. Eminent families passed on medical knowledge from generation to generation. Among them, the Xus from Donghai and the Yaos from Wukang were the most prominent. The Xus were physicians for eight generations, and family members wrote *Xuwang bashi jiachuan xiaoyan fang* (*Empirical Formulas Transmitted by the Xu Family for Eight Generations*) and *Xushi jiachuan mifang* (*Secret Formulas Transmitted by the Xu Family*). Another group was Buddhist and Daoist priests, who were all well educated. They used healing as a means of preaching, and places of religious assembly became medical clinics. Daoism has as one of its principal aims the attainment of immortality, and its priests and followers often sought insights into medicine and bodily care. The most famous Buddhist physicians were Zhi Facun and the monk Shenshi; among Daoists, Ge Hong and Tao Hongjing were well known.

The Tang dynasty was a period of consolidation and innovation. Many medical classics were reorganized and richly annotated. Virtually all of the older classics that have come down to us were revised by Tang physicians, including *Suwen*, *Nan jing* (*Classic of Difficult Issues*), and *Huangdi Mingtang jing*. Manuals listing countless formulas were compiled. Sun Simiao's *Beiji qianjin yaofang* (*The Thousand Gold Pieces Prescriptions—In Case of Emergency*) and Wang Tao's *Waitai miyaofang* (*Arcane Essentials from the Imperial Library*) cataloged medical formulas written in the Wei, Jin, Southern, and Northern dynasties. They deleted redundant material, reorganized the formulas, and categorized them according to illness. These became the most important such books in the history of Chinese medicine.

The Tang emperors paid close attention to the development of medicine, and the government took an active role in promoting education, research, and treatment. Early in this period the Imperial Medical Office (*Taiyi shu*) was founded. As the official medical institute, it was responsible for instructing medical students, transmitting medical knowledge, and holding regular examinations. Its curriculum covered medical theories, acupuncture, massage, and apotropaics. It set the curriculum and also monitored students' progress. Students had to pass examinations before practicing medicine. On the other hand, it was also responsible for medical administration, diagnosis and treatment for the emperor and the imperial family, and medicinal control.

Seizing the heterogeneous medical legacy of previous eras, a centralized government and many individual physicians labored to produce a coherent body of knowledge and practices. Studies of materia medica emerged as a great success. The first official pharmacopoeia, *Xinxiu bencao* (*A New Compilation of Materia Medica*), was completed in 659. For both medical education and daily medical practice, this book became the standard. Emperors Xuanzong and Dezong sponsored the compilation and publication of, respectively, *Guangjifang* (*Formulas for Widespread Benefaction*) and *Guanglifang* (*Formulas for Widespread Benefit*).

China's early medieval period was notable for the revision of medical classics and the com-

pilation of medical formulas and materia medica. Religious, kinship, and governmental groups all played significant roles in promoting medical knowledge.

Indian Influence on Chinese Medicine through Buddhism

One of the traditional Five Sciences (*pañcavidyā*) studied in Buddhist institutions in India, Indian medicine accompanied Buddhism as it spread throughout Asia over the first millennium of the Common Era. The basic principles of Indian medicine were introduced to the Chinese cultural sphere by Buddhist proselytizers and translators as early as the second century. Over the course of the Chinese medieval period (ca. 300–1000 CE), Indian knowledge increasingly influenced ideas and practices in China and soon became an integral part of Chinese medical culture.

Extant Buddhist medical texts from the medieval period include the *Sutra on Buddhist Medicine*, *Secret Essentials of Curing the Maladies of Meditation*, the *Sutra on the Embryo*, and *Ravana's Teachings on Curing the Maladies of Children*. Disease and healing are also mentioned in ritual texts, monastic disciplinary manuals, spell-texts (*dharani*), hagiographies, philosophical

➤ HEALING AND HAGIOGRAPHY

Stories about monks, bodhisattvas, and other Buddhist heroes with magical powers over disease, drought, famine, and other disasters played an important role in Buddhist proselytism in the medieval period. The hagiography of one miracle healer, Jivaka (known in China as Qiyu or Qipo), became particularly popular in China. Known as the “Medicine King,” Jivaka was said to have been an orphan who had learned the healing arts from a great Ayurvedic physician in northern India. According to legend, Jivaka went on to become physician to the Buddha and to perform a number of miraculous cures including abdominal surgery, trephination, and even resurrecting the dead. By the Tang dynasty, the Medicine King had been deified and was being worshipped for salvation from disease. Stories of Jivaka’s exploits were retold widely, inspiring similar tales about other legendary Chinese physicians, and texts produced in his name or containing medical knowledge attributed to him appeared in Chinese throughout the first millennium.

—C. Pierce Salguero

treatises, collectanea (anthologies), and other genres. Many other Buddhist texts mobilize medical ideas as parables, metaphors, or narrative tropes. These diverse texts introduced China to many Indian ideas about the body, disease, and healing that differed markedly from classical Chinese medical doctrines. They also introduced an array of new therapeutic practices, including Indian dietary regimens, medicinal formulas, medicated butter, herbal baths, meditations, visualizations, spells, talismans, repentance, ritual healing, and even surgery.

By the Tang dynasty (618–907), Indian medical knowledge came to exert an appreciable influence on Chinese medicine. Indian medicinal herbs entered the Chinese pharmacopoeia, traveled to Chinese cities along extensive Pan-Asian trade networks, and became important commercial items in Chinese markets. Surgeries and medicines of Indian origin appeared in Tang medical treatises alongside and intermixed with Chinese remedies. Chinese Buddhist monks

such as Zhiyi (538–597) and Yijing (635–713) as well as physicians such as Sun Simiao (581–682) wrote treatises in which they attempted to reconcile Indian medical doctrines with the classical Chinese concepts of Yin-Yang and Five Phases (*wuxing*) and the system of acupuncture meridians (*mai*) and internal organs (*zangfu*).

As with many other aspects of Tang culture, cosmopolitanism and hybridity were important features of Tang medicine. However, during the Northern Song dynasty (960–1127), Chinese medicine began to be standardized and promulgated at the highest levels of the government. Medical bureaus turned to the earliest Chinese medical classics as sources of authority, and overt references to Buddhist knowledge became increasingly scarce in official medical literature.

Nevertheless, Buddhist healing never ceased to be an important ingredient in the Chinese medical marketplace. Throughout the subsequent history of China, Buddhist temples and shrines—particularly those associated with the Medicine Buddha (Yaoshi Fo) and the Bodhisattva of Compassion (Guanyin)—remained active sites for curative prayer and ritual. Buddhist hospitals, hospices, and dispensaries remained a regular part of Chinese urban life. Monks and nuns continued to serve their communities as healers and as organizers of public medical charity. Buddhist ritual and magic continued to be utilized by the sick of all social classes. These aspects of Buddhist healing became an integral part of Chinese popular culture and continue to thrive today in parts of China and Taiwan as well as in communities of the Chinese diaspora worldwide.

Early Medieval Arabic Medicine

Pre-Islamic Arabic medicine is rooted in Bedouin traditional practices in which it was usually women and the elderly who took care of the wounded and general healing via traditional remedies, which included spells and incantations. With the advent of Muhammad (ca. 570-632) and the rise of Islam, these traditional remedies, combined with various treatments mentioned by Muhammad in the hadith (the sayings of the Prophet) became known as Prophetic Medicine or the Medicine of the Prophet, which is still used by many Muslims today.

Early Arab medicine owes its development to the early Arab conquests and expansion, beginning in 634, as the result of which Arabs began to translate and assimilate the vast knowledge of the Byzantines, Persians, and Indians, which included medicine and began late in the Umayyad caliphate (661-750) but flourished particularly during the Abbasid caliphate (fl. 750-ca. 945), especially under the caliphs al-Mansur (r. 754-775), his grandson Harun al-Rashid (r. 786-809), and al-Rashid's son al-Mamun (r. 813-833), centered at Baghdad, the capital of the Abbasid caliphate. The conquests of Alexandria in Egypt and Gondeshapur in southwestern Iran were particularly significant for the development of medicine in Islam because Greek medicine as practiced and taught in Alexandria greatly affected how medicine would be taught in Islamic areas. Moreover, the medical practice at Gondeshapur provided doctors for the Abbasid court as well beginning with Jurjis ibn Jabril ibn Bukhtishu, who treated Caliph al-Mansur in 765. Subsequently the family occupied an important role at the court for eight generations, not only in practicing medicine but also in translating, writing new medical texts, and training doctors. It should be noted that most of these early physicians and translators were either Jewish or

Nestorian Christians (today called Eastern or Syrian Christian).

Masarjawayh, a Jewish physician, was believed to be the first to translate a medical text into Arabic, when he translated the *Pandects* of Ahron of Alexandria (fifth century CE) during the caliphate of the Umayyad Marwan I (r. 684-685), although this is now disputed. A Nestorian Christian physician from Gondeshapur, Masawayh, set up practice in Baghdad. Although well known as a physician and ophthalmologist, he was surpassed in fame by his son, Yuhanna ibn Masawayh (777-857; Latin, Mesue Senior), who was not only a prolific author but also a translator. He was the first to write an original treatise in Arabic on the eye, titled *The Defectiveness of the Eye*. He also wrote a compendium (an encyclopedic work) titled *Perfection and Completion* and numerous other works on subjects such as fever, leprosy, and pharmacology. He was also an avid translator of Greek medical texts into Arabic and was said to have translated many of the medical manuscripts that Harun al-Rashid brought back from his campaign against the Byzantines. Ibn Masawayh was surpassed by his student, fellow physician and translator Hunayn ibn Ishaq (808-873; Latin, Johannitius), in both style and sheer number of translations. He along with his son, Ishaq ibn Hunayn (d. 910) and his nephew Hubaysh ibn al-Hasan called al-Asam ("having withered limbs"; fl. ca. 860), translated about 129 medical works (this excludes Hunayn's translations of other works) mainly from Alexandrian manuscripts, including what became the medical curriculum for Islamic medicine. Of these, Hunayn rendered about 95 of Galen's works from Greek to Syriac (after which Hubaysh translated them into Arabic), another 34 Galenic works directly from Greek into Arabic, and another 15 Hippocratic works into Arabic. Hunayn was also a practicing physician and wrote several of his own works, including 2 on the eye, *The Book of Questions concerning the Eye* and *Ten Dissertations on the Eye*, the latter of which contains arguably the earliest diagram of the anatomy of the eye. Hunayn also wrote a basic text titled *Questions on Medicine*, and his *Introduction to Medicine* became a well-known text in Latin translation.

His corrected version of Dioscorides' *Materia medica* (pertaining to herbal remedies and pharmacology) was also of great influence. Another translator, the pagan Thabit ibn Qurrah (836–901), although more famous in astronomy and mathematics, wrote a medical work titled *The Treasury* that also became a standard medical textbook and contains an early description of both measles and smallpox.

Indian medical works were also translated into Arabic and had wide influence, particularly the *Caraka Sambita*, which is a discussion of surgical procedure at which Indian practitioners excelled. Caraka's description of cataract removal from eyes very likely influenced Hunayn's works. Caraka's *Compendium* (*Caraka sambita*, translated into Arabic as *Saharik al-hindi*), Susruta's *Compendium* (Arabic, *Susrud*), and Vagbhata's *Heart of Medicine* (*Astangabhrdaya*, ca. 600 CE), which combined and organized the information of the two compendia, were available before circa 850 along with another Indian work on poisons, the *Canakya* (Arabic, *Shanaq*). Indian Ayurvedic medicine is similar to Greek humoral medicine; indeed, Greek and Indian medical traditions had likely been influencing each other since Alexander the Great's invasion of India more than a millennium before the flowering of Arabic medicine. Indian medicine differs from the Western tradition in positing only three humors, not four: wind (*vata*), bile (*pitta*), and phlegm (*kapha*). These must be kept in balance with the seven bodily tissues and waste products or else disease results. Although Rabban al-Tabari (ca. 850) included both Indian and Persian medical authorities in addition to Greek authorities in his *Paradise of Wisdom* (possibly the earliest compendium composed in Arabic, written for the caliph al-Mutawakkil), the Greek system would be predominant after 850.

The greatest physician of this early period was Abu Bakr Muhammad ibn Zakariyya al-Razi (ca. 854–ca. 925), known to the Latin West as Rhazes, who, like most Arab scholars, was accomplished in many areas, including music. He wrote over 200 works on logic, philosophy, natural science, alchemy (often tied to medicine), theology, mathematics, and astronomy and 56 on medicine and related areas. Of his medical works, he is most famous for *The Book of Medicine for al-Mansur*, *On Smallpox and Measles*,

and *The All-Inclusive Work on Medicine*. *The Book of Medicine for al-Mansur* is composed of ten books, the first six theoretical (e.g., diet, anatomy, physiology), the last four on practical things such as diagnosis, therapy, special pathology (diseases), and surgery. It was a popular and useful work and became popular in the Latin West as well in the translation made by Gerard of Cremona in 1175 titled *Liber medicinalis ad almansorem*, or simply *Liber almansoris* (*The Book of Almansor*). Book 9 on special pathology circulated alone as the *Liber nonus* (*Book Nine*) in the Latin West, and both these and commentaries on them were published until the seventeenth century in the West. His work *On Smallpox* (measles was only secondarily a concern) was also quite popular and significant, as it treated every aspect of the disease from diagnosis to treatment and was one of the earliest works in the Middle East to do so. It was known in the Latin West as the *Liber de pestilentia* (*The Book of Pestilence*). *The All-Inclusive Work on Medicine* is a compendium that consists of his notes, clinical observations, and quotations from books he read on various subjects, which were compiled, organized, and published after his death. Despite its length and relative lack of organization it was influential, and Faraj ibn Salim translated it into Latin as the *Continens*.

Ali ibn al-Abbas al-Majusi (fl. 983), known to the West as Haly Abbas, brought the compendium to perfection with his work *The Complete Medical Art*, also known as *The Perfection of the Art* or *The Royal Book*, a very well-organized and practical work that reflects al-Majusi's work as the director of the Adudi hospital in Baghdad (founded in 982 by Adud al-Dawlah, r. 949–983). It would be surpassed only by Ibn Sina's (d. 1037) *Canon of Medicine*. Constantine the African (fl. ca. 1080) translated al-Majusi's compendium into Latin as the *Liber pantegni*, and then Stephen of Antioch translated it again into Latin as the *Liber Regius* (*The Royal Book*) in 1127.

Arabic medicine, by the mid-ninth century, was based primarily on the works of Hippocrates of Cos (fifth century BCE and following) and Galen's (d. 216 CE) reworking and development of the Hippocratic tradition. In the Greek humoral tradition, the health of the body is based on maintaining balance and harmony among the

THE COURT PHYSICIAN AND TRANSLATOR OF BAGHDAD

Hunayn ibn Ishaq (808–873), a Nestorian Christian, was a well-known court physician and translator in Baghdad who translated numerous works from Greek to Syriac and Arabic. He also wrote numerous works of his own, including *Introduction to Medicine (Isagoge)*, later translated into Latin. The following is an excerpt:

“Medicine is divided into two parts, namely theoretic and practical. And of these two the theoretic is further divided into three, that is to say, the consideration of the naturals, the non-naturals, and the contra naturals. From the consideration there arises the knowledge of sickness, of health, and of the mean state, and their causes and significations; of when the four humours [*sic*] increase in an abnormal manner or of what may be the causation (*occasio*) or significance of sickness.

Of the Naturals

The naturals are seven in number: elements, qualities (*commixtiones*), humours (*compositiones*), members, energies, operations, and spirits. But some add to these four others: namely, age, colour, figure, and the distinction between male and female.

The Elements

There are four elements: fire, air, water, and earth. Fire is hot and dry; air is hot and moist; water is cold and moist; earth is cold and dry.

The Qualities

There are nine qualities, eight unequal and one equal. Of the unequal, four are simple: namely, hot, cold, moist, and dry. From these arise four compounds: namely, hot and moist, hot and dry, cold and moist, cold and dry.

The equal is when the body is so disposed that it is in good condition and in a mean state, when it has a proper amount of all four.

Of the Humours (De Humoribus)

The humours (*compositiones*) are four in number: namely, blood, phlegm, reddish bile, and black bile. Blood is hot and moist, phlegm is cold and moist, reddish bile is hot and dry, black bile is cold and dry.”

Joannitius (Hunayn ibn Ishaq), *Isagoge*, translated and annotated by H. P. Chomeley, with additional notes by Michael McVaugh, in *John of Gaddesden and The Rosa Medicinæ* (Oxford, UK: Clarendon, 1912), 136, as cited in *A Source Book in Medieval Science*, edited by Edward Grant (Cambridge, MA: Harvard University Press, 1974), 705.

four humors: blood, phlegm, and yellow and black bile, which had corresponding temperaments (sanguine, phlegmatic, choleric, and melancholic, respectively). Health could be affected by or even restored by manipulation of the six nonnatural environmental factors: surrounding air, diet, sleep, exercise, mental (emotional) state, and retention or evacuation of waste. The balance was also maintained by phlebotomy (also called venesection, commonly known as blood-letting) and cupping (putting a heated cup over small cuts on the skin to draw blood).

The human body was viewed as a microcosm of the universe. For diagnostic purposes therefore, in addition to the corresponding tem-

perament, one of the four cosmic elements (earth, air, water, and fire), two of the four primary qualities (wet, dry, cold, and warm) that were associated with the particular element, and one of the four seasons were likewise assigned to each humor. For example, blood (sanguine temperament) was associated with the element of air as well as with the primary qualities hot and wet and with spring. Moreover, the months of the year (distinct from those of the seasons), the signs of the zodiac, and the human ages (childhood, adolescence, adulthood, old age), figured into the system as well.

Hospitals (*bimaristans*) were probably adopted from the Byzantines and the public clinics

described in Indian medical works but were adapted by the Muslims beginning in the late eighth or early ninth century in Iraq. There were several hospitals in Baghdad founded by al-Muqtadir (r. 908–932), his mother, and his vizier. The Adudi hospital (mentioned above) employed 25 doctors of all specialties.

Medicine in India

Three main types of medicine can be distinguished in India during the period 300–1000 CE: ayurvedic medicine, folk medicine, and tantric medicine. Ayurvedic medicine was based on the classical concepts of Indian philosophy and a theory of the humors, folk medicine relied strongly on magical and religious practices, and tantric medicine was more esoteric and mystical in nature. The boundaries between these strands were, however, not clearly demarcated: the treatment of demonical possession through spells formed, for example, part of the eight branches of ayurvedic medicine.

The origins of medicine in India can be traced much further back to, for example, the Vedas and the great epics. In the *Ramayana*, the monkey general Hanuman is sent on a mission to obtain a certain herb that alone can heal the injured Lakshman, and in the *Mahabharata* the harm of a snakebite is undone by the use of spells and cinders. The fear of snakes and poison

and attempts to control them feature prominently in Indian culture. The Buddha is said to have given a charm against snakebites to his disciple Ananda, and in the *Mudra Rakshasa*, a famous Sanskrit play, a physician tries to poison the king, who is, however, saved because the unusual color of the drink is noticed in time.

The word "ayurveda" consists of elements from the Sanskrit language: *ayus* (life) and *veda* (knowledge). Ayurveda is not only a medical system in the sense that it attempts to cure illnesses but instead is a comprehensive science of life that seeks to help people achieve a wholesome life in accordance with their individual constitution as well as with the rhythms of nature. Influenced by Indian philosophy, especially the Nyaya and Vaisheshika systems, ayurveda holds that every object in the world is composed of the five elements of space, air, fire, water, and earth in differing combinations. A central cause of illnesses consists in the excess or deficiency of some of these elements, and the remedy in restoring a healthy equilibrium through, for example, the consumption of appropriate foodstuffs and beverages. Ayurvedic medicine categorizes people into three broad constitutions according to their dominant physical substance: wind (*vata*), choler (*pitta*), or phlegm (*kapha*). Each of these constitutions is taken to have its own delicacies and requirements for diet and lifestyle, recommendations on which can be found in the Sanskrit treatises.

The most fundamental texts of ayurvedic medicine are the compendia by Sushruta and Caraka, which in their earliest versions might have originated around 300 BCE. However, dating is notoriously difficult in the Indian context, and significant changes and additions were made to both treatises over the subsequent centuries. The Sushruta compendium was repeatedly reworked during the centuries up to probably 500 CE, and the Caraka compendium is known to have been completed and edited heavily by a scholar from Kashmir called Dridhabala, probably during the fourth century or somewhat later. Both of these Sanskrit texts remained highly influential during the whole period under discussion. The Caraka compendium was translated into Persian and Arabic and was keenly studied by Arabic authors such as Ibn-Sina (980–1037). In

return, Muslim physicians brought with them their Unani medicine, which had originally been developed from ancient Greek theories and was to rise to prominence in India during the times of the Delhi sultanate and the Mughals.

A fourth-century birch bark manuscript, called the Bower Manuscript after the British lieutenant who purchased it after its discovery in 1890, illuminates the state of medical knowledge in India at the time. The manuscript is made up of seven distinct texts, which are composed in Sanskrit mixed with Prakrit; contains quotes from the Caraka compendium; and explains treatments with powders, clarified butter, the use of aphrodisiacs, and remedies against various diseases. The first part is a treatise entirely devoted to the use of garlic for medical purposes. While many Hindus do not eat garlic because of the plant's stimulating properties, the text describes it as a divine gift that subdues all diseases and even recommends the performance of a garlic festival during the cold times of winter. The instructions for such a garlic health cure include consuming crushed garlic mixed with clarified butter for ten days at sunrise, followed by a period of regular intake of strained garlic juice.

Ayurvedic tradition sometimes speaks of three great medical authorities. One of these three was Vagbhata, although there might have been several authors with the same name rather than one historical person. The most important medical texts attributed to Vagbhata are the *Ashtanga Hridaya* and the *Ashtanga Samgraha*, which might have been composed around the seventh century. The *Ashtanga Hridaya* includes a chapter on insanity, which according to Vagbhata can be caused by a disturbance of the humors, by mental suffering such as the loss of a loved one, or through poisoning. The recommended treatments for insanity include massages with mustard oil; eye salves made of clarified butter combined with other ingredients such as pomegranate, ginger, jasmine buds, and water lily; and harsher methods such as keeping the troubled person in a dried well until emaciated and shock therapies such as scaring the person with tame lions or snakes.

It was often recommended that a remedy should be accompanied by an appropriate mantra

that is a holy syllable, word, or phrase that was invoked in order to aid healing and to pacify the disease. Spells, prayers, charms, and amulets formed an important part of Indian folk medicine, especially when a disease defied rational explanation or when no other protection seemed possible. While folk medicine knows the use of herbs and usually also has a concept of natural illnesses such as cuts and broken bones, its characteristic feature is its magico-religious orientation. Through dream analysis, astrology, and divination, people sought to understand the powers that caused illness but that were largely unseen and unknown. In many cases illness was explained through evil spirits that possess the body, especially of small infants, and the healing rituals included exorcisms that were to be performed on the patient.

From around the eighth century CE, tantric medicine gained a sizable following in India. There were many different tantric cults, the common elements of which were the belief in a dual principle of the male, static Shiva and the female, energetic Shakti, which together form ultimate reality. The tantric movement developed a system of alchemy based on metallic compounds, especially mercury and sulfur. Mercury was identified with Shiva and sulfur with Shakti, sometimes more explicitly with her menstrual blood. The goal of tantric alchemy was to discover elixirs that would give health and eternal youth to the body, an objective very similar to that of alchemists in China, with which India had an active relationship of cultural exchange. The best-known author of a treatise on Indian tantric medicine was Nagarjuna, who probably lived during the ninth century and who should not be confused with the much earlier Buddhist philosopher of the same name.

There are other elements of Indian culture, which, though not medical systems in the narrow sense, sought to promote good health, mainly because control over the body was taken to be a vital factor for spiritual progress. The *Yogasutras* by Patanjali, possibly written in the fourth century, teach various practices for the attainment of higher consciousness through self-discipline. Among the yogic practices are the postures of hatha yoga, exercises for breath regulation, and various forms of meditation,

which have become popularized all over the world as techniques to improve health and well-being. For the yogi, however, health was not an end in itself. The high regard for renouncers who undergo extreme, sometimes permanently disabling austerities shows that the Indian ideal was to value spiritual progress above physical well-being and that it was acceptable to sacrifice one's physical health in the pursuit of a liberated soul.

Medical theorizing in first-millennium India was not limited to the treatment of humans; it also included instructions for the treatment of animals like cows and horses. Most famously, the *Hastayurveda*, which can be dated before the eleventh century, is a comprehensive treatise devoted entirely to the care of elephants. The text is partly composed in verse, and the medical instructions are embedded into a dialogue between King Romapada and the legendary Palakapya, the most distinguished expert on the veterinary care of elephants. The text contains praise on the greatness of elephants, which in India were used for both labor and as displays of royal power, and describes their proper care in great detail, including a wholesome diet and the construction of the stables.

The *Hastayurveda* categorizes various types of burns, wounds, fractures, and diseases and presents the different forms of surgical interventions with their appropriate surgical instruments. The health problems it describes range from supernumerary teeth to parasites living in the ears to the problems being encountered after being pierced by a poisoned arrow. Drawing from the different sources of the Indian tradition, the text deals with elephant anatomy and applies the ayurvedic theory of the humors to elephants but also contains mythological stories on the origin of fever and magical elements, such as mantras to drive out disease.

Byzantine Science and Medicine Translation to Islam

Byzantine science and medicine were characterized, in the words of noted historian of medicine Owsei Temkin, by a combination of tradition and empiricism. From the fourth to seventh centuries CE, scholars redacted, commented on, and organized the works of classical Greek science and medicine. Their selections ensured the survival of the theories of Ptolemy, Galen, Euclid, and others but also addressed practical problems such as calendar dates or the diagnosis of diseases. Their translation into Arabic or Persian in the eighth and ninth centuries was the basis for Islamic science and medicine. Although the association of Greek science and medicine with Neoplatonic philosophy led to conflict with Christianity in late antiquity, it was eventually accepted as part of the Byzantine classical heritage. In contrast, little Greek science was available in Latin during the early Middle Ages, leaving Western science and medicine without a theoretical basis, dependent on folklore. Byzantine scholars in the ninth and tenth centuries produced little new work, but they studied and recopied ancient texts and revived mathematics as part of the curriculum.

The study of astronomy, astrology, and mathematics in late antiquity was centered in the philosophical schools of Alexandria and Athens, where pagan Neoplatonist philosophers and their Christian successors also studied and commented on Aristotle, Ptolemy, and Euclid. Ptolemy's second-century *Mathematical Synthesis* (*Almagest*), *Handy Tables*, and *Planetary Hypothesis*, which gave geometrical models for mathematical calculation of planetary motion basic to calendars and astrology, and Euclid's *Elements* (ca. 300 BCE) were preserved in commentaries and introductions for students by the fifth-century scholars Theon (ca. 335–405 CE), assisted by his daughter Hypatia (ca. 355–415)

and Proclus (411–485). It was in this form that later Byzantium and Islam knew Ptolemy and Euclid. The regular motion of the stars formed the basis for much of ancient science, from visual observation to the mathematical formulas developed to predict motion. Since Greek science and medicine did not draw modern distinctions between natural and occult learning, astronomy and astrology overlapped, and the same scholars wrote in both fields. Astrology used astral data, Aristotelian physics, and philosophical language to predict individual horoscopes (genethliology), identify favorable times for major events (catarchic astrology), and give responses to questions. Ptolemy's astrological treatise, *Tetrabiblos*, remained the foundation for fifth- and sixth-century scholars (e.g., Hephaestion of Thebes), but collections of other treatises and horoscopes also survive from this period. Alchemy—the transformation of base metals into gold—generated a rich literature in this period, both in concrete recipes and in mystical allegories, and, translated into Arabic, helped establish the Islamic alchemical tradition. Stephanus of Alexandria, philosopher and teacher in the early seventh century, brought many of these strands together, editing Ptolemy's *Handy Tables* for use in Constantinople and writing treatises on alchemy and arithmetic and commentaries on Hippocrates, Aristotle, and Plato.

Scholarly doctors in late antiquity, especially in Alexandria, played a similar role in transmitting Greek medical learning and making Galen's work, along with the Hippocratic tradition, accessible. Galen's theoretical approach to all aspects of medicine, contained in voluminous works, was summarized and organized for clarity by Oribasius (ca. 320–400), Julian's court physician; Aetius of Amida (fl. ca. 530–560); Alexander of Tralles (525–605); and Paul of Aegina (seventh century). As practicing doctors, they amplified their selections with applications from their own experience. The range of topics covered was vast, including disease, pharmacology, gynecology, ophthalmology, surgery, dentistry, pulses, and urine lore. Galen's theory of drugs by degrees, for example, was explicated by Aetius of Amida to illustrate a classification of drugs used until the eighteenth century. Alexander of Tralles combined written sources for specific diseases

THEY KILLED HER BECAUSE SHE WAS TOO SMART—HYPATIA OF ALEXANDRIA

Hypatia of Alexandria (ca. 355–415) was the leading teacher of mathematics and Neoplatonism of the philosophic school of Alexandria from about 390 until 415. She grew up in the school as the daughter of Theon of Alexandria, a famous mathematics and astronomy scholar whose commentaries on Euclid and Ptolemy still survive. Hypatia was his best student, and he acknowledged her contributions to the texts. By the 390s she had a circle of students and wrote commentaries of her own on the works of earlier mathematicians, none of which survive. Her teaching is reflected in letters written to her by one of her students, Synesius of Cyrene, who describes her as the “genuine guide who presides over the mysteries of philosophy.” Hypatia taught both Christian and pagan students and was widely respected by Christians, but in 414 she became the victim of a struggle between Christian factions in Alexandria, who slandered her as a magician and witch. She was killed by a mob in 415, and her body was dragged through the streets and burned like a criminal. Christians as well as pagan intellectuals condemned her death. Although she was not the only learned woman teacher of antiquity, Hypatia's fame as a female philosopher and mathematician was unequaled, and her life has been reflected in many later legends and literary works.

—Dorothy de F. Abrahamse

with his own cases and accounts of local folk treatments from his extensive travels as a doctor, while Paul of Aegina's work on surgery and surgical instruments became the standard for later centuries. Byzantine doctors incorporated amulets, magic, astrology, and healing shrines into their treatments, but their advice in many areas is similar to modern practice.

There is little evidence of Byzantine science or medicine in the eighth century, the era of iconoclasm and the struggle for survival against the Arabs, but the era was epochal for the translation of Greek scientific and medical learning into Arabic. The translation movement was initiated by the caliphs al-Manṣūr (754–75) and al-Mahdī (775–85) as they established the ʿAbbasid state in Baghdad. Al-Manṣūr commissioned

translations of secular Greek works to proclaim Islam the true heir of Greek secular learning, in contrast to the anti-intellectualism of Byzantine Christianity, and to meet his urgent need for Greek astrological computation. Translations were also necessary for practical needs of the regime for educated civil servants. Islamic sources mention Ptolemy, Euclid, and Aristotle among the first translations, and medical tradition describes the translation of Galen and Hippocrates through the writings of Oribasius and Paul of Aegina. Syriac and Greek-speaking Christians in former Byzantine territory, often considered heretics by the Byzantine Church, were the first translators of texts, but eventually trained bilingual translators, often Greek, produced the high-quality Arabic texts that served as a basis for the great Islamic achievements in philosophy, science, and mathematics. By the end of the tenth century the crucial works had been translated, and Arabic scholars began to transmit new scientific knowledge to Byzantium and the rest of the world.

Science, medicine, and mathematics were included in the ninth-century Byzantine scholarly revival, now centered in the imperial school in Constantinople, where Leo the Mathematician (ca. 790–869) taught. Renowned for his mathematical skill, he knew astrology, and his library included Ptolemy, Archimedes, and Plato. Leo's reputation allegedly led the caliph to recruit him, unsuccessfully, for his service. Minuscule script, much faster and more economical to copy, was introduced in this period with a massive project of recopying ancient manuscripts on parchment, becoming the source of later Greek texts. Among the earliest were Euclid, Aristotle's scientific works, Ptolemy's *Handy Tables* and *Almagest*, and Paul of Aegina. How these works were studied is unclear, but manuscripts with the marginal comments of tenth-century Byzantine intellectuals still exist. Historians of Byzantine science and medicine are still addressing fundamental questions about their development in medieval Byzantium, but it is clear that the achievements of Alexandrian and Athenian scholars in science, mathematics, and medicine and their preservation in manuscript copies and transmission to Islam were monumental contributions.

Arab Medieval Science

After Muhammad's death in 632 CE the great Arab Muslim conquests of the next 90 years confronted the new rulers with enormous challenges for ruling their now diverse subjected populations. In their efforts to deal with these obstacles they were able to use the learning of ancient civilizations of Greece, Persia, and India. By adopting these intellectual developments of the ancients, Islamic civilization further contributed to advances in science and medicine, which were diffused throughout the Afro-Eurasian ecumene in subsequent centuries.

Ancient Greek and Hellenistic philosophy and science were to have the greatest influence on Islamic currents of thought, followed by the contributions of the intellectual traditions of Persian and Indian civilizations. Following the Muslim conquests, Jewish and Christian physicians from Gundishapur were to be the leading physicians in the Umayyad and later Abbasid dynastical states. Eventually their monopoly on the corpus of knowledge of Greek medicine was broken as ideas percolated into Western Christendom and Asian regions. Alexandria was another center of learning where numerous translations of these texts occurred on a vast scale that allowed for their transnational diffusion. The use of Arabic, which had developed as the lingua franca (common language) of the Muslim world, given the military expansions made under the caliphs, made it possible for scientific knowledge and books to be utilized from Spain to India.

► VETERINARIAN FOR THE SULTAN'S HORSES—ABU BAKR AL-BAYTAR

Arab science in the medieval period made many advances in medicine, surgery, and pharmacology. Medical advances aided both humans and animals. In a society where livestock were important for farming, transportation, and military needs, veterinary advances were most welcome. For medieval Muslims, veterinary care for horses included diet, exercise, physiology, and deformities as well as diseases and their treatments. The treatment of diseases included the use of medicines.

Some of the most important veterinary advances in pharmacology were made by Abu Bakr al-Baytar, who was the chief groom and veterinarian at the court of Al-Nasir Muhammad Ibn Qa-laoun, the ninth Mamluk sultan of Egypt in the early 1300s. Abu Bakr al-Baytar was born in Malaga, Andalusia, in Spain.

Abu Bakr al-Baytar wrote a work titled *A Dictionary of Simple Medicines and Foods* that synthesized then-current medical knowledge. For this book, al-Baytar used over 150 sources. He also listed over 2,000 simples (uncompounded drugs) in alphabetical order. Pharmacists and botanists preceding al-Baytar had been able to identify most of the simple uncompounded drugs described in the *Materia Medica*. These drugs were called “simples.”

Al-Baytar's work, the short Arabic title of which is *al-Jami*, was more than just a list of medical

plants. It was the most complete book of applied biology developed during the High Middle Ages. Using information from a variety of traditions, al-Baytar added to his own knowledge of plants the descriptions of other authors in all the languages that he knew. In addition, using Arabic as his standard language, he was able to give Arabic names to virtually all of the plants described, including those in the pharmacology work of Pedanius Dioscorides (first-century CE Greek pharmacologist and botanist), *De Materia Medica*.

The dictionary produced by al-Baytar combined materials synthesized from earlier works with his own field observations. Like other Arab botanists, al-Baytar conducted field research on plants. He traveled to Egypt, North Africa, Syria, Iraq, Iran, Arabia, and Anatolia as well as Greece in order to collect specimens. His dictionary contains over 1,400 entries and describes plants not previously described by Greek and Roman writers.

Al-Baytar's dictionary discussed animal husbandry, breeding, and animal diseases and their treatments. He also prescribed using animal organs for treatments that followed medical traditions from Aristotle's time. One section deals with keeping birds in Syria and Egypt.

Eventually he settled in Egypt, where he became its head pharmacist. He died in Cairo in 1340.

—Jack Waskey

Within two centuries the bulk of Greek and Hellenistic science had been translated into Arabic, and subsequently the antiquated Syriac versions fell into disuse. An emergent generation of scientists studied Greek scientific knowledge in Arabic translation. Along with valuable contributions from ancient Persian and Indian scientific documents, Greek knowledge was grafted and built upon a more sophisticated and enlarged body of medieval Arabic science.

From about 900 to 1200 CE Arabic science (named as such given that it was in the Arabic language) flourished in the lands of Islam. However, not all were Muslims, as many were Jews and Christians who resided in the Muslim realms. During this period dynamic innovations took place with advances in medicine, astron-

omy, mathematics, architecture, and technology that percolated throughout much of North Africa, the Levant, Mesopotamia, Persia, and Spain.

The great social value of medicine was further stimulated by support from the caliphs and other Islamic rulers. With official government support Muslim physicians and scientists interested in medicine wrote numerous medical treatises, which steadily contributed to the growing body of knowledge. By the ninth century Baghdad was the center of medical study of the Islamic realms. From the tenth to the eleventh centuries CE other regional centers of medical study and practice were in competition with Baghdad. By the end of the fourteenth century Damascus had become the center of medical science. During this time Greek and Hellenistic

medical science had been absorbed, and new medical knowledge developed as an end result.

Arabic medical science made advances in anatomy, blood circulation, surgery, and pharmacology. Arabic study of biology and botany aided the development of pharmacology. Pharmacology was also advanced by physicians who catalogued and identified all the simple medicines derived from plants and herbs. By the twelfth century a number of pharmacological encyclopedias were available throughout the Islamic realms. One encyclopedia, *al-Jami li-Mufradat al-Adwya Wal-Aghdhiya* produced by ibn al-Baytar, was widely read even in Christendom for its discussion of both medicines and health foods.

Astronomy was of great practical interest in the Muslim world. Before the advent of Islam, Arabs had developed an astronomical lore for practical matters such as night travel in the desert and what would become the “Islamic problems” associated with worship. As a place of Muslim worship, a mosque has to have a *qibla*, which is a mark in line with the Kaaba in Mecca. The prayers of the worshippers will then be made in line with the qibla. Other problems have to do with time keeping by solar observations so that the five times of prayer each day occur on time. In addition, lunar observations of the crescent moon have to be made just after sunset so that the lunar calendar of Islam can be kept. These practical problems encouraged the study of astronomy as a means of finding viable solutions. Observatories, such as the observatory at Baghdad under the Abbasid caliphate, were sponsored by various rulers.

The first astronomical works translated into Arabic were of Persian and Indian origin. However, studies of the extant translations show that these works were usually a syncretic mixture of Persian, Indian, and Greek astronomy, an example of the cultural diffusion of science during this period. Within a short time Arabic astronomers recognized the superiority of Greek astronomy. The work of Ptolemy was given the Arabic title *Almagest*. Nonetheless, these astronomers continued to build on the legacy of the ancients by instituting their own discoveries and innovations in the field.

Zij al-Sindhind (astronomical tables of Sind and Hind) by al-Khwarizmi was written in the

early ninth century and contained astronomical tables from both Indian and Greek sources. In the tenth and eleventh centuries, advances in mathematics, notably trigonometry, were used to augment developments made in astronomy. As ever larger and more numerous observatories were built, innovations in mathematics allowed for more accurate observations. One of the great practitioners of medieval Islamic science was Aby Rayhan al-Biruni (973–1048). He wrote over 150 works on astronomy, mathematics, geography, mineralogy, metallurgy, pharmacology, and other scholarly subjects. One of his most valuable works was *al-Oanun al-Masudi (Canon Macudicus)*, which was a synthesis of Greek, Indian, and Arabic astronomy.

Al-Biruni along with others contributed to the advancement of theoretical astronomy. Al-Biruni and Ibn Sina (Avicenna) debated the Aristotelian legacy. Al-Biruni rejected a number of Aristotle’s physical theories on motion and on the orbits of heavenly bodies. By 1200 CE two astronomical schools developed. The Maragha School was centered at Maragha (in present-day Azerbaijan). It was more mathematically centered in its treatment of astronomical problems. The other school, in Andalusia, was more philosophically oriented and focused on planetary problems.

Simultaneously, advances in astronomy were matched by developments in mathematics. The Arabs had inherited a system of finger reckoning called *hisab al-jummal*. It used the order of the letters of the Arabic alphabet as a way of denoting numbers. This method was really limited to simple arithmetic. The introduction of Hindu arithmetical symbols of nine digits and a zero established the basis of the modern system of mathematics used throughout much of the world. It also provided a way to work with decimals and with place values.

In the nascent field of algebra a considerable number of contributions were made by the mathematician Al-Khwarizmi who wrote *Kitab al-Jabr wal-Maqabala*, the first algebra book. Arab mathematicians not only advanced the field of mathematics but also applied their findings to other disciplines such as geography or optics. In the case of geography, mathematics was used to calculate the precision of the location of Mecca, which for worship purposes was of practical

concern. Other practical uses for mathematics included construction and irrigation.

Early Medieval Chinese Alchemy

Alchemy, a science involving the transformation of metals into gold in an attempt to discover an elixir of life, has been practiced in various cultures around the world throughout history, and it was practiced widely among Daoists in China during its early medieval period.

Alchemy in Daoism focused not only on the transformation of metals but also on the physical, mechanical, and biochemical structure of the human body. It is therefore often referred to as physiological alchemy. A strong interest in longevity, health, and immortality occurred in the roots of Daoist thought that emerged in early Daoist writings of China's Classical Period (700–220 BCE). However, it was the *fangshi* (masters of the formulae) of the Qin (221–206 BCE) and early or Western Han (206 BCE–8 CE) dynasties who first experimented with alchemy. This group, which was also highly influential in the transformation of Daoism into an organized religion during the later Han, practiced various alchemical techniques in its pursuit of immortality. In the fourth century CE members of Shangqing (Supreme Clarity), an important branch of Daoism, embraced the alchemical tradition. At this time, Daoists began to understand alchemy not

only as a means to physical longevity but also as one through which spiritual refinement and transcendence could be accessed.

An important figure in the history of alchemy's relationship to Daoism is Ge Hong (287–347 CE). Ge's famous work, the *Baopuzi* (*Book of the Master Who Embraces Simplicity*), detailed methods of preparing and ingesting elixirs. Ge's work emphasized alchemy as a manner through which human bodies could be transformed into those of immortals.

During the Tang dynasty (618–906 CE) alchemy in China broke off into two different forms of Daoist practice: *waidan* (external alchemy) and *neidan* (internal alchemy). Initially seen to exist together as one method through which immortality could be obtained, in the Tang dynasty both forms of alchemy were understood as separate methods by which practitioners could cultivate their bodies. However, external alchemy, which flourished throughout the Tang, is often seen to have preceded internal alchemy, which became highly developed later on during the Song dynasty (960–1279 CE).

External alchemy focused on the examination of elements external and foreign to the human body and the finding of ways by which these elements could be used for purposes of longevity, immortality, and self-cultivation. In this form of alchemy, the alchemist typically ingested pills or elixirs that had been transformed

THE ELIXIR OF IMMORTALITY

In their search for an immortal elixir, early Chinese alchemists experimented with various substances and created a drug called cinnabar, which was produced from mercury, a metallic element of high toxicity. Although they understood that ingestion of such drugs could be harmful or fatal to the human body, many Daoist practitioners still swallowed the often lethal potions, believing that consumption of the concoctions would lead to their immortalization. Many emperors who ruled during the Tang dynasty (618–906 CE) also died after having ingested special alchemical elixirs made from various substances, including mercury and gold. They also believed that they were immortalizing themselves.

—Anna Hennessey

from various mineral and herb ingredients. Alchemists prepared these ingredients according to recipes that referred to the cosmological principles of yang (creation) and yin (dissolution and return), viewed as the two primal forces of the universe in Daoism. Daoists viewed combinations of yang and yin to be regulated by the five elements of the world: wood, fire, earth, metal, and water. Fire, the physical manifestation of yang, and water, the physical manifestation of yin, both played crucial parts in the work of the alchemist, who heated and cooled the various ingredients used in the alchemical creation of pills and elixirs.

Internal alchemy did not focus on utilizing any substances external to the human body in its search for an elixir of life. Instead, this form of alchemy professed that all of the necessary ingredients in obtaining immortality existed within the human body. Through dietary and meditative exercises, practitioners of internal alchemy therefore focused their attention on cultivating the yin and yang energies believed to dwell inside the body. In the Song dynasty, internal alchemy revolutionized Daoism, advocating a cultivation of mind and body and incorporating elements of both Confucianism and Chan Buddhism into its practices.

Early Medieval Arabic and European Alchemy

Alchemy is often referred to as the precursor to modern chemistry, which in some sense is an accurate depiction. Medieval alchemists did produce substances such as nitric and hydro-

chloric acid as well as sodium carbonate. In addition, elements such as arsenic and bismuth were isolated and identified for the first time. However, the alchemy practiced in the ancient and medieval worlds was much more than a kind of primitive chemistry. It was a combination of mysticism, philosophy, religion, and science. And in practice, it often involved more art than science.

First developed in antiquity, alchemy evolved independently in various parts of Europe, Asia, and North Africa. There is some dispute as to its exact origins, but most scholars agree that it involved ideas concerning nature as well as the various craft traditions in antiquity. In the West, the Greek works were well circulated throughout the Mediterranean world. In particular, Aristotle's works as well as those of other popular Greek philosophers found a home in the Egyptian city of Alexandria. In Egypt, the interest in alchemy blossomed considerably. It became known as the art of *chemeia*, which came from the black soil of the region. Many of the works were attributed to the mythical Hermes Trismegistos (the thrice-great Hermes). This figure is most likely based on the Egyptian god Thoth. Hermes was the supposed author of the *Hermetic Corpus*, which was written in the second and third centuries CE and expounded an esoteric Hellenistic philosophy that involved Jewish, Roman, and Egyptian mystical concepts. The Hermetic writings would not be well known in the Middle Ages but would later be idealized by renaissance writers and philosophers such as Marsilio Ficino, who dated the authorship to the time of Moses. This is, however, a clear indication that alchemical authors of late antiquity were influenced by various sources. These often included Christian, Gnostic, and Neoplatonic elements. Medieval alchemy, like most areas of science in the Middle Ages, was most profoundly influenced by the works of Aristotle but also owed much to cultural contacts with Chinese and especially Indian thought.

Medieval medicine was based on Galen's second-century doctrine of humor theory, which hypothesized that the body was made up of four humors: blood, black bile, yellow bile, and phlegm. Similarly, Aristotle's four base terrestrial elements—fire, air, water, and earth—

would be an integral part of medieval alchemy. Various combinations of these elements would produce different substances. Eventually the emphasis would be on gold and producing it from other sources (particularly other base metals). Gold in some areas was related to immortality, which was a particular fascination among medieval alchemists.

The interest in the early medieval West was quite limited. This lack of interest perhaps stems from the interpretation by Saint Augustine (354–430) of the importance of science. Augustine characterized the learning of science as an “empty curiosity.” Only after the rediscovery of the Greek corpus of scientific thought in the High Middle Ages, hastened somewhat by the twelfth-century renaissance, did Westerners begin to take a significant interest in most areas of science. This included alchemy.

With the limited interest in alchemy in the Christian West, the major developments came from the Arab world. There was an immediate interest in alchemy among Arab scholars who came in contact with Greek alchemical lore and the synthesis of it with Chinese, Persian, and Indian texts and traditions.

One of the first Muslim alchemists is believed to be Prince Khalid Ibn Yazid, who worked in the late seventh and early eighth centuries. From that point on, Islamic interest in alchemy flourished in centers of learning throughout the Near East. In fact, the word “alchemy” itself is derived from an Arabic word, *al-kīmiya* or *al-khīmiya*. The Greek variation on the word is to add the prefix *al-* to *chumeia*, which is defined as “to cast together” or “weld.”

The eighth-century alchemist Jabir Ibn Hayyan was probably the most renowned of the Arabic alchemists and is often referred to as the “father of chemistry.” A polymath, Jabir is given credit for many chemical procedures, such as distillation and crystallization, and the invention of much scientific apparatus. He is often credited with the discovery of such elements as arsenic, antimony, and bismuth and the processes to produce such substances as sulfuric and hydrochloric acids. Jabir may have been the first to introduce the idea of transmutation. He proposed that by rearranging the qualities (hot, cold, dry, moist) of one metal, it could be transformed into

➤ PHILOSOPHI LAPIS—THE PHILOSOPHER’S STONE

The eighth-century alchemist Jabir Ibn Hayyan may have been the first to introduce the idea of transmutation. He proposed that by rearranging the qualities (hot, cold, dry, moist) of one metal, it could be transformed into another. From this came the philosopher’s stone, the holy grail of medieval alchemy. It is a well-developed concept in Arabic and later Latin literature. The stone provided a substance that could supposedly turn lead and other base metals to gold. It may also have been associated with an elixir of youth, but many scholars now believe that they were two different concepts. In the West, the stone is closely associated with Nicholas Flamel (1330–1417), the late medieval alchemist whose work revolved entirely around the stone and who was reputed to have actually found it. Flamel and the philosopher’s stone have been a permanent part of medieval lore ever since.

—Jace Stuckey

another. From this came the philosopher’s stone, the holy grail of medieval alchemy. It is a well-developed concept in Arabic and later Latin literature. The stone provided a substance that could supposedly turn lead and other base metals to gold.

With the significant interest among the Muslim scholars, there tended to be various interpretations, concerns, and functions among Islamic alchemists. On the one hand, there was the magical and supernatural aspect that dealt with everything from number mysticism to the formation of special elixirs that held untold powers. On the other hand, there was a practical side that focused more on medicinal chemistry. Scholars and alchemists such as al-Razi (ca. 860–925) and Avicenna (980–1037) tended to be interested in the practical medicinal aspect of alchemy. In al-Razi’s most important work, the *Book of the Secret of Secrets*, he discusses the mystical side of alchemy, including transmutation and elixirs, only briefly. The bulk of his emphasis is on practical chemistry, equipment, and laboratory operations. He also composed a general classification of all substances: animal, vegetable, and mineral. There were then subcategories for the major

classes. Other important achievements included the development of a distillation process and the use of hydrochloric and nitric acids to dissolve metals.

In general, alchemy was just one aspect of the broader Islamic interest in science. Although Arab scholars were working with alchemical texts in the early eighth century, Latin scholars would not do significant work for another four centuries. Although alchemy was ultimately condemned by the Church, there were some minor contributions by the monastic community of the early Middle Ages. These contributions often came in the simple form of preservation. Many works of antiquity only exist today because they were copied by monks working in scriptoriums. Gerbert of Aurillac (later Pope Sylvester II), working in Spain in the late tenth century, was one of the first Christian scholars to assimilate Islamic science and introduce it to the Christian West. The close contact between Christians and Muslims in Spain would help foster a renewed interest in science among Christians.

Abu Musa Jabir ibn Hayyan— The Father of Chemistry

Jabir ibn Hayyan (ca. 721–ca. 815) is often called the “Father of Chemistry” because in his practice of alchemy, he used experimentation and created various laboratory processes and devices still in use today such as the alembic, which made the distillation process more systematic for experimentation purposes. More-

over, because of his theory of balance, he believed that substances could be combined (particularly with the alchemical sulfur and mercury) in specific proportions to produce new substances or transmute them into other known substances. His use of proportions is held to be a precursor to the law of constant proportions in chemistry. He is also credited with the discovery of various acids including sulfuric acid, which was known in the Middle Ages as vitriol. Then, by distilling salt with sulfuric acid he discovered hydrochloric acid, and by distilling sulfuric acid with saltpeter (which some also credit him with discovering) he discovered nitric acid. Moreover, he created what is known as *aqua regia* (royal water, or king’s water) by combining nitric acid with hydrochloric acid in specific proportions (1:3, respectively). Aqua regia, which can dissolve gold, had obvious applications for both extracting gold from the ground (or another substance) and purifying it as well and also has uses for engraving. He also discovered how to isolate other acids, including citric, acetic, and tartaric acids. Additionally, he developed several processes that aided or improved leather tanning, cloth dyeing, cloth waterproofing, and steel manufacture and along with it the prevention of oxidation (rust), and in a process still used today in glassmaking, he utilized manganese dioxide to alleviate the green tint caused by iron. He is also credited with discovering the element bismuth, as well as antimony, mercury oxide, lead acetate, arsenious oxide, and cinnabar.

Jabir ibn Hayyan’s system for determining specific weights, densities, ratios, and so on of a specific substance in relation to another was exceedingly complicated. His method relied on a Pythagorean and Neoplatonic numerological system based on the magic square, in which the four numbers of the lower left square (1, 3, 5, 8) add up to 17, but the system was further developed by Jabir to include his numero-alphabetical system in which he assigned a numerical value to each of the Arabic letters.

In addition to the complexities of his thought, Jabir wrote in such a cryptic language that his works were considered nonsensical by many, which may be the origin of the term “gib-

berish.” As Jabir himself said, “One must not explain this Art in obscure words only; on the other hand, one must not explain it so clearly that all may understand it. I therefore teach it in such a way that nothing will remain hidden to the wise man, even though it may strike mediocre minds as quite obscure; the foolish and the ignorant, for their part, will understand none of it at all.”

■ Introduction: Early Medieval Military Technology

In the period 300–1000 CE (as in other periods) military technology and proficiency in military skills were important to virtually all societies throughout the globe. In societies where states had formed, support of the military enterprise was one of the principal functions, perhaps the principal function, of the state, and military technology was, after the technology of agriculture, most important. In this essay, technology concerning infantry and cavalry as well as fortifications, sieges, and naval warfare will be discussed.

The infantry, or foot soldiers, was important and the most numerous branch of most early medieval armies. Infantry fought with thrusting and slashing weapons, such as swords, pikes, battle-axes, and the like. Often they wore leather body armor and sometimes chain mail as well as metal helmets. The Vikings, who fought mainly on foot, sometimes wore chain mail shirts into battle. Early medieval infantry also usually carried shields, usually on the left arm. The Romans used long shields with which they could protect their bodies above the knees, and these could be connected to their neighboring shields to form a wall. Shields were made of leather, cotton, wood, bamboo, wicker, turtle shells, and, less often, metal.

Another variety of foot soldiers was those using missile weapons: bows and arrows, longbows, compound bows, atlatls (spear and dart

throwers), crossbows, and repeating crossbows (in China). The bowmen and particularly crossbowmen stood or knelt behind freestanding shields (in Europe called *pavis*). These bowmen and crossbowmen were not usually considered the same as the infantry who fought with swords and spears because they required a different type of training and organization. Only when the infantry were provided with gunpowder weapons (after the period of concern by this essay) did they fight mainly with projectile weapons. In the Americas, bows and arrows were not introduced until early in the first millennium CE. Many groups fought with atlatls, a type of handheld spear or dart thrower. By the fourth century, the bow and arrow was diffusing southward through North America, resulting in disaster for those groups who did not yet have the new weapon. By 1000 CE, the bow and arrow had probably spread to South America, though many Mesoamerican peoples clung to the atlatls until European contact in the fifteenth century.

The other major branch of the land forces was the cavalry, who were usually horsemen but also cameleers and elephant drivers. The invention and diffusion of the stirrup early in this period revolutionized cavalry warfare because it enabled the horseman to more easily stay mounted as well as enabled him to put the force of his weight and the horse's momentum in his lance thrusts. The stirrup was invented by the

Chinese or adapted by them from the steppe nomads in the fourth century. From the Chinese it spread in all directions: to Korea and Japan, to India, and across the Eurasian steppe. The Muslims adopted it probably in the late seventh century, and in the eighth century the Franks learned of the stirrup. Tradition has it that Charles Martel's army learned of it from the Arabs at the Battle of Tours in 732.

The adoption of stirrups led to the breeding of heavier horses, battle chargers strong enough to carry a heavily armored rider and the armor that covered the horse. To carry this weight of metal chain mail, the horse required special feed: clover or alfalfa hay and grain. The feudal system in Europe may have evolved as a response to the need for a social system that, in the absence of a strong state, could supply the resources to pay for the expensive horses and armored knights.

Early medieval peoples built fortifications in the traditional pattern with heavy earthen or stone walls. China's border fortifications, which had existed for centuries, were of rammed earth until replaced with stone in the Ming dynasty. The Sassanian Persians built defensive walls in the Caucasus and to the east of the Caspian Sea. In the ninth century, two defensive walls were constructed in western Europe: Offa's Dyke, built by the king of the Anglo-Saxon kingdom of Mercia along the border with Wales, and the Danewirke, an earthen and timber wall across the Jutland peninsula for defense against Carolingian incursions.

In the early medieval age, defensive walls of stone protected most cities. In Europe, local strongmen built fortified castles, first of timber and after the ninth century increasingly of stone. With the increasing construction of fortifications, warfare devolved largely into siege warfare. In siege warfare, there was very little innovation from the techniques of antiquity. The army conducting the siege tried to surround, or throw a ring of circumvallation around, the city in an attempt to starve the besieged. The attackers would use battering rams, siege hooks, ladders, and various types of rock-throwing artillery: ballistae, catapults, trebuchets, mangonels, and onagers. The defenders would fire large crossbows, mobile crossbows, and, in China, repeating crossbows through arrow slits and loopholes.

The attackers often tried to undermine the walls by tunneling, mining, and sapping or attempted to get over the walls by building siege towers or constructing ladders.

Another important branch of military technology was naval warfare. The most important innovation in naval warfare during this period was the invention of Greek fire by Byzantine scientists in the late seventh century. With this invention, a kind of flamethrower, it was possible to burn the enemy ships, making unnecessary the ramming and boarding of the enemy craft, as had been the practice previous to this.

—*Wilfred J. Bisson*

Early Medieval Defensive Walls

Early medieval defensive walls were necessary because the protection offered by centralized governments had broken down in western Europe. The lords and population of a region had to protect themselves from invaders such as Vikings. Although variations existed depending on local geography and climate, most defensive walls followed the same general pattern.

For most of its existence, the Roman empire had been far superior militarily compared to its neighbors. Roman armies on campaign built temporary fortifications, but permanent fortifications existed mostly on the borders of the empire. As Rome declined militarily, engineers began to build defensive walls around cities and towns that might be attacked. With the end of centralized Roman authority, these fortifications fell into disrepair.

By the fifth century, local populations in the West were forced to defend themselves. The earliest fortifications were built by common people and were relatively simple structures called burhs. A burh consisted of a wooden palisade or wall with a surrounding ditch. In times of invasion, peasants would flee to the burh with their possessions and help defend it.

As local lords increased their power over communities, they built their own fortifications, which doubled as the lords' residences. These fortifications served as refuges during attacks and also helped to control access to important locations. Some were built in towns, where the garrisons could better control the local popula-

tion. Known as motte-and-bailey castles, these defensive fortifications were built of earth and wood. The central feature was a high mound of earth, or motte. The motte was either natural or man-made. Often, the sides of the mound were reinforced with stones or brush, so it could be as steep as possible. A wooden wall was built around the top of the mound, and a multistory tower was built inside. The tower doubled as the lord's home and a final line of defense. The tower was originally known as the dungeon or donjon. Height was an important feature of the motte because it allowed the garrison to see hostile forces approaching. The additional height reduced the effectiveness of attackers' weapons while increasing the striking power of defensive fire.

A lower mound with a greater surface area was constructed nearby. Known as the bailey, this mound included buildings necessary to maintain the lord. They included stables, storage buildings, and residences for the garrison. A separate wall surrounded the bailey. Both the motte and the bailey were normally enclosed by a ditch. The ditch might be filled with water, spikes, or other obstacles. Wooden drawbridges connected the motte and bailey. An outer wooden wall often surrounded the entire motte-and-bailey complex.

Wooden castles of the motte-and-bailey type survived until the twelfth century. They had many advantages. Wood was plentiful during this time period. Many were also built on the sites of old Roman fortifications. They could be erected very quickly, especially if the materials had been gathered together beforehand. These early defensive fortifications were not able to withstand the increasingly sophisticated siege weapons and techniques that emerged in the twelfth century, however. Returning crusaders brought incendiary weapons such as Greek fire, which could destroy wooden structures. Artillery such as trebuchets were able to overcome the wooden walls as well. Thanks to increased knowledge in stoneworking and shortages of wood, stone castles began to replace the older wooden walls.

Pickering Castle in North Yorkshire, England, is an early motte and bailey castle—a simple, timber construction built on top of a grassy mound, surrounded by earthen banks and ditches. Early medieval strongholds were usually built of earth and wood. A ditch surrounded the enclosure, which was usually placed on a hill. Other natural defensive features, such as rivers, were used to limit attackers' approaches. A fortified keep was located on a raised hill toward the center, allowing defenders to fire on any invaders that penetrated the outer wall. (Skyscan/Corbis)

Forts and Castles

The Romans were master engineers who constructed fortified towns and outposts throughout their empire. The frontiers were studded with garrison forts known as *castra* (sing. *castrum*), the origin of the English place name “-chester” and the word “castle” and its Romance variants (*château*, *castel*, *castile*). They preferred to build walls and towers in dressed stone but adapted to local conditions, utilizing rough stone, brick, and wood as necessary. Towers,

which could be round or square, reinforced the corners of the wall structures and were placed along the walls to shorten the length of less-sturdy stretches. The towers provided excellent views of the countryside and elevated platforms from which arrows and other missiles could be launched against an attacking enemy. Since these extended out from the wall, men in the towers could provide cross fire that helped protect the walls themselves from tunneling and ramming. The camps were well laid out on a square grid pattern, the larger being provided with amenities such as baths and temples. They tended to be located on high ground and at strategically valuable points such as mountain passes, ports, and river crossings.

With the defeat or withdrawal of the Roman legions from the western empire's frontier areas, the fortified towns and *castra* came to be occupied by a mix of local folk and recently arrived Germanic peoples. Both Celts and Germanic peoples had long built military camps protected by palisades of wooden logs and understood the defensive value of the fortifications that fell into their hands. Even so, endemic war, a lack of skilled masons, and frequently shifting borders meant that many of the Roman *castra* fell into ruin. In Italy, savvy warlords, bishops, and later Carolingian counts often maintained the city walls that had first appeared in the third century, thereby preserving some elements of urban life and administration. Embattled early medieval kings and other lords—King Alfred of England (r. 871–899) is the best known—had strategically placed in their territories Roman *castra* refortified with stonework and towers in imitation of earlier Roman models. Thirty of these revived English *castra* and other military forts were christened burghs—from the Germanic word for a fortified place (also -burg, borgo, burgos, -borough)—and played key roles in Alfred's defense against the hostile Danes in the later ninth century.

Otherwise unfortified villages, hilltops, and other defensible points also acquired fortifications in the form of rings of ditches and earthworks of the excavated soil. A wooden palisade of vertical logs ringed the top of the earthworks. The interior of the palisade featured a catwalk or running platform from which protected de-

fenders could view the countryside and hurl missiles. Within the palisade was a broad flattened area that could be several acres in size and in which scores or even hundreds of people lived and worked as a village. These simple ring forts of circular ditches with high interior ramparts surmounted by a wooden palisade constitute the earliest proper medieval castles. Smaller and simpler versions served as the residences of local warlords and their families and entourages. Similar structures appeared along the southern frontier of the Rus with the steppe nomads of central Asia, later giving way to larger and more sophisticated fortified villages.

Freestanding stone tower building revived in the Viking era, perhaps originating in the Irish round towers that served as lookout and protective points for monastic settlements. Stone towers (keeps, donjons) were clearly superior to wooden defenses because they could be built higher and sturdier and were far more fire resistant. The earliest known northern stone square keep was built in the mid-tenth century at Doué-la-Fontaine, France. Others quickly followed, both on the European continent and in beleaguered Britain. Some surviving Anglo-Saxon square church towers may have begun as fortifications. Within, stone corbels or brackets that extended from the walls served as platforms on which plank floors were set, allowing multiple stories for storage and living quarters. The uppermost floor was a perch for observation and defensive fighting. Like earlier Roman structures, these were often crowned with crenellations, the toothlike features behind which defenders could fight.

The Byzantine empire relied on the traditional Roman fortifications of walled cities and *castra*. Early Muslim armies captured and occupied many of these, borrowing their forms. They translated them across the growing Islamic empire, as in the Iberian *alcazaba* (fortress) at Baños de la Encina, built in the 960s on the Christian frontier. One of the earliest Muslim architectural works is the seventh-century fortress of Qasr al-Kharanah in Jordan, a compact structure with tall dressed stone walls, round corner towers, and a double gate. In desert regions, adobe brick often replaced stone as the principal building material, proving quite sufficient at

withstanding both the dry climate and the simple technology of marauding Bedouins.

China had long utilized sophisticated frontier fortifications, the most famous of which was its northern Great Wall. Elsewhere, Chinese forts varied from simple ditch and rampart structures to large stone enclosures protected by sturdy towers and sophisticated mechanical weapons. Farther west, Turkish peoples adopted Chinese forms, fortifying their towns (*balıqs*) with double and triple rings of walls and even moats. Indian towns and villages were also protected by often intricate structures of brick or stone, and where these were less available, as in Kashmir, simpler timber works sufficed.

Battering Rams, Catapults, and Other Preexplosive Artillery

Much medieval warfare consisted of sieges and attacks on fortified locations. Sophisticated machines were often used to successfully capture a city or other fortification. These weapons and the techniques with which to use them were common to different cultures.

Chinese military thinkers devoted much attention to siege techniques in their writings. Manuals described the need to bring all useful materials, supplies, and people into a city facing attack. The territory around the city was to be devastated, so the attackers would have few resources available. In response, attackers used a wide variety of weapons. Catapults may have appeared as early as 700 BCE in China. They were definitely in widespread use by the third century CE and came in various forms. One was a rotating version that could be turned on its

frame to fire in different directions. Others were counterweighted trebuchets, which had greater range and destructive power than most early gunpowder weapons. Unusually, the Chinese never used torsion to power their catapults. Instead, large crews of men pulled on ropes to provide power for the catapults.

The Chinese also used large numbers of crossbow weapons in sieges. Known as arcuballistas, they were able to hurtle projectiles at least 200 yards with accuracy. Originally they used only one bow, but by the fifth century, multibow arcuballistas were being used. These flat-trajectory weapons were greatly feared since their bolts could penetrate any armor and were often used to snipe at individuals.

Chinese siege weapons threw many types of projectiles. The most feared were incendiary devices intended to set a besieged city on fire. Oil-soaked cotton or other flammable materials were used. Recipes for noxious gases and even gunpowder grenades were available for attackers as well.

Chinese siege machines also included cloud ladders, which were scaling ladders on wheels or artificial tunnels, covered with fireproof hides to protect breaking through a wall.

In medieval India, many forts were built to control important areas or to intimidate neighbors. Siege warfare was not very well developed at the time. Mechanical devices called *yantras* are mentioned in accounts of sieges, and they apparently included catapults and crossbow weapons. Catapults were employed to throw flaming missiles into the forts, but their successes were limited. Crossbows were used to hurtle javelins into the forts. Mining under the walls was also used, but most forts were built on bedrock that prevented that tactic. Assaults using mobile towers were used but rarely succeeded. Elephants were also employed to push down gates when possible. The most successful siege tactics used in India were starvation and bribery.

Arab warriors apparently learned about catapults through trade with the Chinese. Known as *manjaniq*, Arab siege engines appeared in the seventh century and used similar technology. Teams of men pulling on ropes provided the power, while a shooter aimed and made adjustments as needed. Successes in sieges helped

Reconstruction of an elevated battering ram. Early medieval siege machinery built on the siege engines of the Classic Period. (Private Collection/Alinari/The Bridgeman Art Library)

make the rapid expansion of the Muslim empire possible.

Unlike other peoples, the Byzantines had full access to Roman technology. Military manuals described how to carry out sieges against fortified positions. The preferred method was to starve out the enemy, reducing the risk of friendly casualties. Mining was also considered an important siege weapon. Greek fire was used on some occasions. Few examples of Byzantine employment of catapults and other siege engines are given by contemporary writers.

During the early Middle Ages in western Europe, pitched battles between armies were relatively rare. Most conflicts took place within the vicinity of the numerous fortifications that were built during this time. To overcome these early castles, soldiers had to find ways to break down the walls and force their way inside. To a large extent, they relied upon technology that had been inherited from the Romans.

One of the earliest weapons used in sieges was the battering ram. The most primitive versions were simple tree trunks. Later peoples added improvements. By the early Middle Ages in western Europe, the battering ram could be a complex weapon. The heart was still a large wooden beam 20–100 feet long. The greater the mass of the beam, the more effect it would have

on the walls it struck. The beam was reinforced by metal bands around the body of the beam to keep it from splitting. The head of the ram was covered in iron to have a greater impact against the walls or gates it struck. Often, the metal covering resembled the head of a ram, leading to the name. The beam was suspended by ropes or chains from a framework built around the battering ram. Wheels were made for the framework, so the battering ram could be pushed up to a wall or gate. To protect the soldiers who would work the battering ram, a protective roof, or penthouse, was built over it. The penthouse had steeply sloping sides so that rocks and other heavy objects thrown from above would be deflected. To protect the battering ram from incendiary devices thrown by the defenders, the penthouse was covered with layers of leather, sand or earth, and felt. This shielding was usually kept wet by the attackers.

A variation of the battering ram was the bore. Instead of the flat or rounded head of the battering ram, the bore had a metal point that was aimed at mortar between the stones in a castle wall. Both variations were known as the tortoise because of the protective covering, the slow approach to the fortification being attacked, and the similarities between a tortoise's head poking out of its shell and the head of the battering ram emerging from under the penthouse.

Other methods of attacking and defending fortifications included various kinds of artillery. Like the battering ram's technology, these machines were inherited from the Romans. They were known by various names but generally fell into two categories. The first was a machine that fired large bolts or arrows in a flat trajectory. Known today as the ballista, this engine looked very much like a large crossbow. In reality, it consisted of two arms, each inserted into a mass of twisted ropes. The ropes provided torsion when the arms were drawn back by a strong rope. A large arrow or bolt was placed in a groove between the arms. When the arms were released, the ballista could throw a 50-pound weight up to 1,200 feet. Ballistas were usually effective against groups of soldiers and could also throw incendiary devices, which could set wooden walls on fire. They were complex machines and required considerable expertise for accurate work.

The other type of nonexplosive artillery used during the early Middle Ages was the catapult. It was often referred to as the onager, after the wild ass with a powerful kick. Europeans also referred to it as the mangonel. The mangonel had one wooden arm with a sling or a rounded bowl at one end. The other end was inserted into twisted rope or animal sinew. The rope or sinew was tightly twisted. When the arm was pulled down, the tension increased. After loading, the arm was released. It struck a wooden crossbeam when it reached the perpendicular, giving extra energy to its launch. Light mangonels could be transported from place to place, while larger versions were constructed on the spot of a siege. Ammunition for the mangonel included stones and incendiary devices. The stones could break down walls, while incendiary devices could set fire to wooden walls or buildings inside a fortification. Dead humans or animals were also thrown inside a besieged town or castle, either for psychological effect or in an attempt to spread disease. A light mangonel could hurl a stone weighing about ten pounds up to 300 feet. Larger versions had a range of up to 1,500 feet. Range was important, since weapons that were set up too close to a fortification could come under fire by archers, ballistas, or mangonels within the walls.

The artillery of the early Middle Ages required a trained crew to be effective. These men could be considered the few truly professional soldiers who served during this time. They had to be able to construct their weapons, either from pieces transported with them or from material found at the siege. They also needed to be able to calculate ranges and determine how to correct after observing misses.

Greek Fire

Greek fire was one of the most destructive yet mysterious weapons of the early Middle Ages. It had both a physical and psychological impact on its victims. Its creation and use required a level of military sophistication that was not seen again in Europe until the twentieth century.

Artwork and written records indicate that fire was used in sieges at least since the Assyrians. Early incendiary weapons included mixtures of sulfur, pitch, and charcoal that were placed against walls or thrown into fortified places. Often these missile weapons consisted of a vessel, wrapped in a burning cloth, that would break on impact. The hope was that the projectile would smash against something flammable, resulting in a general fire. These weapons were known by a variety of names such as wildfire.

Greek fire was an improvement on early inventions. It is generally accepted that Greek fire made its appearance around 673 CE. Medieval historians credit Callinicus, an architect or engineer from Heliopolis in Syria, as its inventor. Callinicus had fled from the Muslims who overran Syria. Modern historians believe that the actual inventors were alchemists in Constantinople. They received information of discoveries by alchemists in Alexandria before that city was conquered by Muslims. The formula was supplied to the Byzantine emperor and the military. The term “Greek fire” was applied by Western crusaders at a later date. The Byzantines considered themselves to be Romans and referred to it as liquid fire or marine fire.

The ingredients and exact formula for Greek fire were a closely guarded secret. It was described as a wet dark liquid. Modern historians suspect that oil or an oil product was a significant part of the formula. Alchemists in the

Twelfth-century illustration shows how Greek fire could be projected from one ship to another. It was widely feared, and once a ship was set on fire, the flames could rarely be put out. (Prado, Madrid, Spain/The Bridgeman Art Library)

eastern Mediterranean were familiar with oil and many of its properties. Writers describing Greek fire's use indicated that it floated on water, so a major component was probably a light liquid oil product. Modern theories about its ingredients include naphtha, sulfur, niter, quicklime, and phosphorus. The ingredients were apparently heated in a cauldron to create the mixture. Various histories indicate that it either ignited upon contact with water or that it was lit by a small flame when projected. Metallurgical advances by the Byzantines allowed them to create metal siphons or pumps that could project the mixture a considerable distance.

Greek fire was used primarily at sea. Ships could easily hold the large equipment necessary to use the mixture effectively. Long bronze tubes projected from the ships and carried the Greek fire toward its target. Tanks with pumps could be carried inside the ships. Because opposing ships were built of wood, they burned easily when set alight. Greek fire floated on the water, so near misses could still inflict damage on an enemy vessel. Water would not put out the fire; inflammable materials, such as sand, were the best method. These inflammable materials were not usually available at sea, so once a ship was ignited, there was little hope of saving it.

The first recorded use of Greek fire was in 678 CE. A Muslim fleet had established itself at Kyzikos in preparation for a siege of Constanti-

nople. A smaller Byzantine fleet attacked the Muslims. At first, traditional methods were unsuccessful. Then the Byzantines unleashed their Greek fire. The effect was nearly instantaneous. Those Muslim ships that were nearby were set aflame. When water could not put out the fires, the remainder of the fleet panicked. The Muslim fleet was virtually destroyed, with the estimated loss of 30,000 men. The second recorded use was in similar circumstances when a Muslim army and fleet attacked Constantinople in 717. Once again, the Byzantine ships were able to set the opposing fleet on fire, destroying their opponents and forcing them to raise the siege.

Greek fire was sometimes used on land as well. Handheld pumps, with a small supply of mixture, were carried into battle. Small flames were used at the nozzles to set the liquid on fire as it sprayed out. While useful in sieges, Greek fire was less effective in open battle, since opponents could maneuver out of the way or strike at the soldiers who carried the pump.

Because the formula was a closely guarded secret, the Byzantines used Greek fire on only a limited basis. The Muslims eventually developed their own version, but it was relatively weak and used most often on land. The secret to Greek fire was lost by the time Constantinople fell to the Muslims in 1453. Although other incendiary weapons and mixtures later appeared, none matched the original Greek fire.

Early Medieval Infantry and Cavalry Weapons

The peoples of Eurasia depended on similar weapons for the infantry and cavalry during the early medieval period. Pole weapons such as

spears and lances were most common and were used by men on foot and on horseback. Swords were less common and usually indicated a social status, such as in the Indian and European armies. Bows and arrows were widely used and played a role in preparing an opponent for an assault. Technological differences were few. The best example might be the Chinese invention and widespread use of the crossbow. The specific details of other weapons depended to some extent on the formations and tactics used by the different armies.

Unlike some other regions during this time, China was ruled by strong governments that could draw on centuries of military experience. Commanders were skilled at using combined arms in battle. Uniform weapons were supplied by the governments. Cavalry was the dominant arm, but disciplined infantry formed a base for maneuver. Individual cavalymen and infantrymen were armed with long spears. At the beginning of this time, infantry pole weapons such as the *ji* included several blades for slashing or hooking opponents as well as points for thrusting. They were succeeded by simpler long spears and lances with simple heads. One reason for this evolution may have been that infantry formations became tighter to form greater obstacles to cavalry charges. Most infantry and cavalry were also armed with swords for close fighting. The *dao* became the weapon of choice. It was a single-edged slightly curved saber intended for slashing attacks. A substantial number of the infantry were armed with bows.

The standard Chinese bow was a composite reflex bow, very powerful and accurate in the hands of a trained warrior. The Chinese were also the inventors of the crossbow, which may have appeared as early as 1000 BCE. It was especially common among soldiers defending fortified positions. The crossbow had superior range and penetration compared to other bows but was hampered by the time it took to cock it. The careful integration of different types of infantry into Chinese formations reduced this disadvantage.

In India and South Asia, invaders from central Asia forced a reevaluation of traditional fighting techniques. Huns and Turks interrupted the internecine warfare that had followed traditional

Anglo-Saxon sax from the ninth century CE. With this heavy iron weapon, a warrior could chop or stab, or it could be thrown as a javelin or spear. (HIP/Art Resource)

patterns for centuries. With their emphasis on cavalry, the invaders confirmed the low level of respect in India for infantry. Most infantry consisted of peasant conscripts or lower social classes. They were poorly trained and armed and were expected to play a minor role in battle. Some infantry used longbows, but the use of compound bows was limited to the nobility. Swords were highly regarded but rare among the infantry. Most carried a long spear about ten feet long known as a *sakti*. Cavalry weapons were similar but of better quality since cavalry was composed of the nobility. Bows and arrows gained favor among the Indian nobility, especially in battles against the invading Huns. A short composite bow of horn and metal was developed for easy use on horseback. Elephants formed their own corps and were most important for their psychological impact. Soldiers mounted on elephants were armed with bows and long lances.

In the Byzantine empire, at first the army drew upon a Roman heritage but was composed of soldiers recruited by individuals. The main striking force consisted of heavy cavalry, but armored spear-bearing infantry provided a secure base for maneuver. After the reforms of the seventh century, heavy infantry was armed with a spear and short sword. Most also carried a short ax known as the *tzikourion*. It had a standard blade on one side and a spike on the other side.

The spike could penetrate any armor encountered by the Byzantines. Light infantry were armed primarily with bows and arrows along with javelins. They carried a dagger and short sword for close combat, but a lack of heavy armor discouraged their use.

The Byzantines' opponents during most of this time period were Muslim armies. At first, horses were scarce among the Arabs, and most fighting was done by infantry. They were armed with spears up to ten feet long known as the *qanab*. It had a large blade with a strong shaft. Blocks of infantry braced the butts of their spears against the ground to create defenses against charging cavalry. Infantry was also armed with short straight swords for thrusting in close combat. After 1000, Muslim craftsmen perfected the curved scimitar, which could be used in slashing attacks. Bows and arrows were common among Arab infantry, but they used simple bows that were limited in their power and penetration.

The weapons of the infantry and cavalry of the early medieval period in Europe were largely based on technology inherited from the late Roman empire. Many of the nomadic and Germanic tribes, especially those with limited contact with the Romans, had their own specialized weapons, but most could be classified as edged or pole weapons. To a large extent, cavalry used the same basic weapons as infantry, although they were modified for use from horseback. Few dramatic advances in weaponry occurred during this period.

With the breakdown of centralized Roman authority, most soldiers had to provide their own weapons. An individual's financial standing determined what weapons he used. The most common and simplest weapon was the spear, although it was known by various names. The basic spear consisted of a sharp pointed metal head on a wooden shaft. The shaft was sometimes reinforced by metal strips to make it harder to break or cut. The small amount of metal made the spear cheaper and easier to produce. Depending on the length, a spear could be thrown or used as a thrusting weapon. Spear carriers tended to stand close together, allowing them to make a dense hedge of spears to discourage cavalry. Cavalry used lances, which were similar to spears but had longer shafts.

When European peasants were called into service as infantry, they sometimes brought their farm tools. One of the most common was a fork mounted at the end of a shaft. Scythe blades and pruning hooks on shafts were also basic infantry weapons for those who could not afford anything better.

Edged weapons were more expensive. Their possession ordinarily marked a soldier as a person of means. Because sword making required hours of work by a blacksmith working layers of steel and iron together, swords took on special significance and expense. Many soldiers during the early medieval period used Roman short swords (about two feet long). They were gradually replaced in western Europe by the *spatha*, a straight two-edged blade about three feet long. Similar weapons included the *sax*, used by the Saxons, that was a long single-edged weapon similar to a machete. These weapons were used more often for slashing, as opposed to the Roman practice of stabbing.

Other edged weapons that were common during this period were battle-axes. The Franks who occupied Gaul gave their name to their throwing axes, known as the *francisca*. Viking warriors often used long-handled battle-axes. Battle-axes could often smash shields or cut through armor. They also could inflict blunt-force trauma, breaking bones and causing internal injuries. Later variations included heads with daggerlike points or spikes. These heads could be used to exploit gaps in an opponent's armor.

The bow and arrow was also used in western Europe in the early Middle Ages but was less common for a number of reasons. One was that European bows were relatively weak. Most were constructed on single pieces of flexible but strong wood, about three feet long. Near the end of the period, stronger compound bows were made by gluing pieces of horn or sinew to the wood to make it less flexible. Archers in several areas also lengthened the wooden bow, giving it greater strength and leading to the famous long-bow. Another reason for the bow's rarity was the time required to master it. Only those who were able to devote large amounts of time could use it effectively. Archers learned to use different types of arrowheads for different types of targets, including those intended to pierce ar-

mor. A skilled archer could hit targets up to 600 feet away and fire ten arrows per minute.

Early Medieval Body Armor

Body armor varied widely across the medieval world. While all armor was intended to protect its wearer, different cultures used different materials. Iron, steel, leather, and cotton were all used. Different environments and combat tactics used by the cultures determined what kinds of armor were prevalent and provided the best balance between mobility and protection.

The Chinese were among the most technologically mature users of armor during this time. The first iron armor had appeared several centuries before the Common Era. Lacquered leather armor continued to be widely used until the sixth century CE, however. Chinese craftsmen recognized that flexibility was important and developed a system of lamellar construction. Small plates, at first of leather and later of iron or steel, had small holes drilled in the corners. Leather or silk cords passed through the holes to tie the plates together. They overlapped, providing continuous protection while improving the wearer's ability to move. The individual plates and the cords were often colored, indicating to what

unit the individual belonged. Various styles of armor existed depending on the individual's duty. Most had high collars to protect the back of the neck. Cavalry armor had a flared bottom to protect the upper legs. The lower legs were protected by leather guards.

Because cavalry was the decisive arm, most infantry did not have armored suits. Their personal protection was usually limited to helmets that provided protection for the neck, sides, and cheeks, and they also had shields. Shields were normally constructed with a wooden framework with leather or lacquered cloth stretched over it. Leather shin guards completed their protection.

The importance of cavalry was emphasized by the development of horse armor in China. Heavy armored cavalry forced a decision through impact, aided by the adoption of the stirrup by the fourth century. Lamellar armor for their horses increased the cavalry's ability to deliver this attack. Separate face masks, chest and shoulder armor, neck plates, and side and rump armor gave the horses protection while allowing them much freedom of movement.

Armor development in the Indian subcontinent lagged behind that in China and remained largely static during this time period. Body armor was usually provided by individuals according to their economic status. Three types of armor were used. The best quality was *lobajalika* (chain mail), which came in full- or waist-length versions. A hood provided protection for the head. A lesser-quality armor consisted of metal breastplates known as the *lobapatta* that were held in place by leather straps. The armor most common among the poor consisted of thick quilted cloth. *Sutrakankata* consisted of multiple layers of cotton or possibly silk cloth with cotton, wool, or hair padding. It provided reasonable protection against arrows and cutting weapons. Tribesmen used as mercenaries throughout India were known for their use of animal skins, complete with hooves and horns, as body armor.

Most Indian warriors wore metal helmets by the sixth century. Others wore turbans with multiple folds of cloth for protection. Neck guards made of metal were common. Protection was also provided by individual shields. Shields were either for parrying or passive protection.

Model of a soldier that was discovered in a shrine at Ming-oi. Painted stucco, Tang dynasty. (Werner Forman/Art Resource, NY)

Parrying shields were small and were used with swords. They were usually made of metal. Larger shields were made of wood, wicker, or bamboo. They were sometimes covered with leather made from rhinoceros or elephant hides.

The Byzantine empire inherited the technology and traditions of the Roman empire. By the sixth century, however, Byzantine body armor had been influenced by innovations from the East. The decisive arm was the heavy armored cavalry, the cataphracts. They were protected at first with full-length mail coats. Later, the Byzantines adopted lamellar armor suits along with similar protection for their horses. Horses were also protected by platelike shoes to prevent spikes from hurting their hooves. Armored arm and leg guards, along with small circular shields, completed the cavalryman's protection. Armored heavy infantry wore similar lamellar armor. Many Byzantine soldiers were raised by provincial authorities, and their body armor was often less complete. Soldiers in the first and sec-

ond lines might have had full mail or lamellar armor along with steel helmets. Those whose position was in the rear, however, made do with leather or quilted cloth armor. Their head protection was limited to felt caps instead of helmets. Light infantry also wore little if any armor.

The Muslim armies that faced the Byzantines adopted similar body armor. Previously, the Arab warriors had used felt or quilted body armor. Their experiences against Byzantine heavy cavalry taught them the value of mail shirts and lamellar armor. At first, heavy infantry was considered the most important part of the Arab armies, and heavy cavalry was expected to dismount and fight as needed. Warfare against horse archers from central Asia convinced the Muslim leaders of the benefits of combining archers with heavy cavalry. Lightweight armor for horses followed. Light metal helmets also were adopted by most Muslim warriors. Shields in Muslim armies were made of wood or hardened leather.

Early medieval body armor varied widely throughout Europe. Much of it was inherited from the Roman legions, while the barbarian tribes from outside the empire brought their own. Much of the emphasis, however, was on mobility and therefore light equipment. As the centralized authority of the empire disappeared, individuals were usually forced to purchase their own armor or to do without it. The cost of such armor and the time and skill required to make it were important factors in driving up its price. Many of the peasants who served in medieval armies during crises had little or no personal armor except for a shield.

The body armor of Roman soldiers was gradually discarded during the fifth and sixth centuries. The laminated breastplate known as the *lorica* was replaced by a tunic on which overlapping scales of metal or horn were sown. More movement was possible when wearing the *squammata*, as it was called. Chain mail tunics were also introduced in this time period. Chain mail consisted of tiny interlocking rings. Called *byrnie*s, the long chain mail shirts provided effective protection against the slashing weapons most often used during this time. Short sleeves provided some protection for the arms. Cavalrymen wore similar but longer armor. Their mail shirts usually were split in front and back to make sit-

ting on a horse easier. The longer skirts also provided some protection for the upper legs. The lower legs normally had no protection other than high leather boots. By 1000 CE, most warriors had added a chain mail hood called a coif to protect their heads and necks. Plate metal reinforcements were sometimes added to the *byrnies* of the chest area. Those who could not afford chain mail often wore armor made of boiled leather.

Although some barbarians prided themselves on their lack of body armor, most warriors protected their heads with helmets. During the early period, deep Roman helmets were common. They provided protection for the neck and usually had nasal and cheek guards. Helmets were developed by barbarian tribes that were quite different. Known as *spangenhelms*, these helmets were relatively shallow and covered the tops of the heads. They were made of an iron or bronze framework with iron or horn segments. As time passed, more helmets were made in a single piece. They became more conical to better deflect blows from above. A nasal guard was added, but the remainder of the face was usually uncovered.

An individual's body armor was completed by a shield in most cases. The shield was made from a light but tough wood. Linden was the preferred type. The shield would be covered with leather, which added protection. This covering would also help hold the shield together if it was broken into pieces by a blow. A metal rim was usually fixed to the edge of the shield for greater strength. Round shields were most common, but oval shields were used by the Byzantines. Kite-shaped shields were used by Vikings and later by the Normans. The center of the shield usually had a circular cutout. On the inside, a metal handgrip allowed the soldier to hold the shield. On the outside, an iron boss or stud covered the cutout to protect the user's hand and to provide room. In some instances, the boss was pointed and could be used as a weapon.

Diffusion of Stirrups in the Afro-Eurasian Ecumene

The stirrup was one of the most important advances in societies that depended on horses for warfare and travel. The stirrup allowed riders to steady themselves and have a more secure seat on their horses. In warfare, riders with stirrups could use the momentum of the horse to increase the force of a thrust from a lance or the slash of a sword. Without stirrups, a careless rider could well end up on the ground. The stirrups helped make the horseman the dominant figure in warfare and society. During the period between the end of the western Roman empire and the crusades, the use of stirrups spread to the Middle East and into Africa. Although some traditionalists resisted their introduction, the value of stirrups eventually overcame the objections.

The first saddles had no place for a rider's feet. To mount, the rider had to leap on the horse or use a platform that let him step onto the horse's back. Early saddles also did not help secure the rider, since his feet simply dangled on either side. Riders were less effective in combat without stirrups as well. Archers were less accurate, since they could be jostled while shooting. Riders armed with lances or swords depended on the power of their arm to strike at other riders or soldiers on foot. Trying to use the horse's momentum in a charge could more often result in the rider being thrown off his horse than in increased damage to another soldier.

➤ CATAPHRACTS

The adoption of stirrups by the Byzantine Army was an important step in increasing the effectiveness of their heavy cavalry. Known as cataphracts, these disciplined professionals were already the core of the Byzantine Army, thanks to their superb equipment. The cataphract was protected from head to foot. A conical helmet protected his head and had a horsehair tuft colored to indicate to which unit an individual belonged. Flexible armor protected his body, from neck to upper legs. The armor consisted of small scales fastened to each other usually by leather or silk, which allowed considerable movement. Leather boots or metal greaves protected the cataphract's lower legs, while his hands were protected with metal gauntlets. A small round shield was attached to his left arm, leaving both hands free to control his horse or wield weapons. A chain mail curtain hung from his helmet to protect his neck and face. Even the cataphract's horse was armored, with scale armor protecting the head and front body and legs. A separate piece of armor might protect the rear of the horse. Weapons used by the cataphract included a powerful short composite bow, a lance, and a long sword. A battle-ax and dagger were also carried. Although the cataphract was trained to use all these weapons, they were wielded more effectively after the stirrup gave him more stability as well as the ability to stand up in the saddle and deliver a powerful downward blow.

—Timothy J. Watts

The forerunners to stirrups were toe loops attached to the saddle. Depictions of these devices appeared in India during the second century BCE. Their effect was limited, and they could have been dangerous to a rider who was thrown. Also, the toe loop was only practical in warm climates.

The first practical stirrups date to the fourth century of the Common Era in northern China. They appear to have been invented by the Chinese and spread to the nomadic tribes that ranged through this area. The stirrups spread westward as the tribes migrated toward Europe. The exact date of their arrival in Europe is unclear, but stirrups were unknown to the Huns who arrived in the fourth and fifth centuries. A

hundred years later, the Avars migrated from the east and brought the stirrup with them.

The Avars were enemies of the Byzantines, and their mounted archers were particularly effective against the Byzantine Army. During the wars against the Avars in south-central Europe, Byzantine observers realized that stirrups gave their archers greater stability, especially when their horses were moving. Gradually, they copied the Avars and attached stirrups to their saddles. The use of stirrups was described in the *Strategikon*, a treatise on military science probably written in the early seventh century.

Archaeological evidence indicates that early Byzantine stirrups were very similar to modern ones. They consisted of metal (usually iron or bronze) rings, with a relatively flat bottom on which the rider could rest his foot. The bottom was often reinforced with a metal rib to allow a rider to stand in the stirrups without breaking through. A metal extension at the top of the ring had a slot for a leather strap that attached the stirrup to the saddle. The adoption of the stirrup furthered the development of the armored cavalryman as the core of the Byzantine Army. Although armored lancers had been in use earlier, the stirrup increased their effectiveness. Wearing lamellar armor for greater mobility and flexibility, these armored horsemen were known to the Byzantines as *cataphracts*. They were highly trained professional soldiers, able to use a lance or a bow equally well. The stirrup allowed them greater stability, and it also permitted them to brace themselves when making a charge or fighting in a melee. A cataphract could hold his lance tightly and use the horse's momentum to deliver a powerful thrust against an enemy without fearing that he would fall off. More prosaically, stirrups made it easier for heavily armored men to get on and off their horses, especially in the field.

The Byzantines' rivals to the east were the Sassanid Persians. They had a long tradition of powerful armored cavalry units armed with lances in their armies, similar to the cataphracts in the Byzantine Army. The Sassanid cavalry apparently learned about the stirrup from battles against the Turks, to their north. The stirrup's introduction among the Persians appears to have been later than that of the Byzantines, and some art produced just before the Arab conquest

failed to show stirrups being used by riders. Use of the stirrup by the Sassanid Persians was never as widespread as among the Byzantines.

The rivalry between the Byzantines and the Sassanids was upset by Arab invasions during the seventh century. Beginning in 633, Arab raiders began to penetrate both empires' territories. Under Muhammad, the Arab infantry became more disciplined than previously and was the most important part of the Arab armies. Arab cavalry combined mobility and firepower to disrupt its opponents on the battlefield but was especially useful for reconnaissance and pursuit. At first, Arab cavalry played only a limited role. Experience against the armored cataphracts eventually convinced Arab leaders that they needed similar units. The capture of the Persian empire by 650 gave them the resources to accomplish this.

Although Arab warriors quickly learned about stirrups, cultural factors prevented their widespread adoption for some time. Arab poets, such as al-Jahiz, derided the stirrup as leading to warriors becoming effeminate. Traditionally, Arab riders mounted their horses by leaping from the ground over the back or the side. Using the stirrup as an aid was believed to be unmanly. As Muslim cavalry became more and more armored toward the end of the seventh century, stirrups became undeniable necessities for riders. Arab craftsmen modified their stirrups to include more of a platform to support the entire foot instead of a relatively simple ring. Sometimes the inside edges were also sharpened, allowing them to serve as spurs.

Beginning in 639, Arab armies invaded Egypt and moved westward across North Africa. The

region had been a center of horse breeding and mounted warfare for centuries, and the Arabs brought their use of the stirrup with them. Local peoples, such as the Berbers, had been exposed to Byzantine use of stirrups but seem to have adopted them only after the Muslim conquest. By the time Spain was invaded in 711, use of stirrups seems to have been the norm for riders in North Africa.

Stirrups were adopted in western Europe in the eighth century. When the Carolingian ruler of the Franks, Charles Martel, met an Arab army at the Battle of Tours, the Frankish army consisted mainly of heavily armored infantry, while the Arab army was largely lightly armored cavalry, riding with stirrups. Although the Arabs lost the battle, the Franks were so impressed with the Arab cavalry that they swiftly raised their own stirrup-equipped cavalry. In a very short time, stirrup-using cavalry dominated West European combat. The introduction of stirrups in western Europe is said to have led to the rise of knighthood, chivalry, and feudalism.

The spread of stirrups to sub-Saharan Africa did not follow for centuries because of the limited use of horses in those regions.

■ Introduction: Mathematics and Astronomy in the Early Medieval Age

In the early medieval age, by a remarkable coincidence, India and the Mayas were at the forefront in developing mathematical concepts. In both areas, scholars developed the concept of zero as a placeholder and as a number.

Some historians speculate that the Indians developed the concept far beyond the proto zero sometimes suggested by Greek mathematicians because of the Buddhist theologian's idea of the void, the nothingness that results when

the devotee detaches himself from desire. Among the Maya also, the zero concept may have derived from a sort of religious mysticism, as the Maya sign for zero was a veiled eye, a potent symbol.

From the fifth through the eighth centuries, India experienced a flowering of scientific achievements in mathematics and astronomy. Indian astronomers anticipated Copernicus's heliocentric theory by about 1,000 years, calculated the size of the earth, and correctly plotted the movements of many heavenly bodies.

The Arabs learned the Hellenistic mathematics of the Mediterranean together with that of the Indians and after the ninth century further developed the discipline of algebra. Indeed, the word "algebra" derives from Arabic roots. Other important developments in Indian math were improvements in trigonometry and algebra. Two of India's unique gifts to the world were the decimal numbering system, with its notation in Arabic numbers, and the Fibonacci sequence (a natural numerical sequence found in many natural phenomena, from the spiral of leaves on a twig to the double helix of DNA strands) originally developed by the Indian mathematician Virahanka in the sixth century but introduced to Europe by Leonardo of Pisa (Fibonacci) in the twelfth century. After the twelfth century, Indian and Arab achievements in mathematics and astronomy were available, in Latin translations, to the Europeans, but that fact did not trigger a flowering of European mathematics and astronomy until the European Renaissance.

The Chinese had their own sophisticated tradition of mathematical and astronomic investigation, and even though they were aware of Indian achievements in these fields, they were not greatly influenced by them. It was not until the fourteenth century that Arabic astronomy began to impact China.

—Wilfred J. Bisson

Mayan Astronomy

Astronomy was extremely important to the Maya. Their view of the universe conceived of the heavens, the earth, and the underworld as parts of an integrated system. Human activities needed to follow certain patterns if the harmoni-

ous relationship was to continue. Astronomy told the Maya about the seasons and about when certain rituals should be performed and even predicted disasters and upheavals. Mayan astronomy was passed along to the civilizations that followed, including the Aztecs.

The Maya believed that the sun, the moon, planets, and other celestial bodies represented various gods. They carefully monitored their movements across the sky. Each type of body was believed to reside in its own layer of the 13 levels of the heavens. Human sacrifices and prayers were necessary to strengthen the gods, such as the sun and the moon, as they journeyed each day. In return, the gods brought gifts to the earth such as rain.

Mayan priest-astronomers studied the skies and recorded their observations. They recognized that most heavenly bodies changed their track across the sky on a daily basis. Mayan astronomers were most interested in where the heavenly bodies rose and set on the horizon on different dates. Thanks to their proficiency in mathematics, Mayan astronomers developed two accurate calendars. The first was a ritual calendar with 13 months of 20 days each. This calendar was apparently based on the cycles of the moon. The second calendar was a solar one and had 365 days. The Maya realized that the two calendars would have the same starting date every 52 years. This ending of this cycle was viewed as a time of great change and uncertainty. Later civilizations in Mesoamerica adopted the Mayan calendars.

The Mayan astronomers also paid great attention to tracking other heavenly bodies. The moon was seen as the representation of a female deity. They understood that eclipses involved the sun and the moon and developed mathematical tables to predict eclipses. Because eclipses were seen as significant events that might presage disaster, these tables allowed the priests to prepare people in advance. Because observations were recorded over centuries, at least from 300 CE onward, correction sheets were included with tables of observation.

Venus held a particular interest for the Maya since it was connected with the god Quetzalcoatl. They recognized that Venus rose in the morning during part of the year and in the eve-

The Mayan calendar was quite accurate, thanks to their extensive observation of the moon's positions. Mayans saw time as being organized into multiple cycles. (Corel)

ning at other times. Its rising in the morning was considered a time of bad luck, so most Maya stayed inside during that time.

The Pleiades star cluster was viewed as the center of the stars. When it appeared in the mornings, the Maya knew that planting season had appeared. Other constellations indicated the time of year by the times in which they appeared or disappeared over the horizon.

Astronomy had an important effect on Maya civilization as a whole. Rulers were anxious to be seen as having a connection with the heavens. They claimed descent from the gods. Representations of rulers usually included bands of stars and other heavenly bodies. Battles and wars were fought according to the fortuitous positions of planets such as Venus. The appearance of comets, known as stars that smoke, was seen as a warning of the death of an important person.

Mayan buildings and cities were arranged according to the heavens. For example, the main street in the city of Teotihuacan was aligned on the spot on the horizon where the Pleiades would arise. Specific buildings were sometimes oriented so that they could be used for observations. Another building at Monte Alban was built in the shape of an arrow around 300 CE. Five of the brightest stars at that time set in line with the point of the arrow. The steps of the building were in line with where the star Capella arose near the time when the sun reached its zenith over the city. Other buildings had narrow windows aligned with the points at which the sun

would set on the summer and winter solstices. Other openings were set so that the sun would light up the interior of rooms on specific dates, such as the spring and fall equinoxes. Zenith tubes were dug in the earth so that the passage of the sun overhead would light up the bottom of the structure.

Chinese Astronomy and Astrology

In the early medieval age and indeed until much later, most Chinese savants, like their Muslim and European counterparts, did not differentiate between astronomy and astrology. In Chinese astronomy, the basic supposition was that all events and occurrences, terrestrial and celestial, could be explained by discovering the fundamental regularities pervading the cosmos.

The Chinese believed that the motions in the heavens were signs by which the intentions of the universe were indicated to the emperor as veiled instructions. It was incumbent on the ruler to demonstrate his legitimacy by conforming to the order of the universe. It was the obligation of emperors to conduct the imperial rituals in conformity with the instructions encoded in celestial events.

For this reason astronomy and astrology, the study of the heavens, were an important governmental function as well as a jealously guarded state monopoly. All dynasties supervised astronomers very closely and, as part of their governing apparatus, maintained an astronomy agency whose head, the imperial astronomer, was a high-ranking and highly remunerated official. Each succeeding Chinese dynasty, to strengthen its claim to legitimacy, felt it necessary to reform the calendar by "correcting the beginnings of

years and months.” Calendar reform, in all dynasties, was the main function of the Imperial Astronomical Bureau.

The great Western historian of Chinese science, Joseph Needham, claimed that Chinese astronomers “were the most persistent and accurate observers of celestial phenomena anywhere in the world before the Arabs.” The Chinese excelled in observational astronomy, though they were not as likely as their Indian and Western counterparts to use these observations in constructing cosmological theories and models.

Premodern Chinese approaches to the heavens and asterisms have no clear-cut analogues to the Western distinction between astronomy and astrology: the term *tianwen* (“patterns of heaven/nature”) comes closest (heaven in its original sense of heavenly bodies, etc.). Nevertheless, scholars of Chinese science and astronomy argue for interpreting the ideograph *li* (modern Chinese for “almanac,” “calendar,” “diary”) as astronomy (conventionally, the study of the composition and physics of space); they take *tianwen* as analogous to astrology (conventionally, the interpretation and application of astronomy to life on earth). Given the current Western stance toward astrology in the general situation of knowledge (vs. entertainment), the student of Chinese culture may consider all of these as seriously as they would modern astronomy.

Ideas of heaven/nature and its patterns are inextricably tied to Chinese science, cosmology, politics, philosophy, and ritual. The Chinese devised some of the earliest and most accurate methods for predicting the paths of heavenly bodies, developing highly sophisticated time-keeping systems and applying these to calendrical arts. Records of observations of heavenly bodies appear well before 1000 BCE in China. Attention to astrophysical movements, especially deviations in regularity, interpreted as portents, was driven by the belief in heaven, or *tian*, as sentient and expressive of human action. Tian was all knowing and all powerful. As such, it determined when human governance was corrupt and retaliated accordingly by visiting upon humans destructive or inauspicious circumstances. Similarly, auspicious omens expressed approval of human rule. This concept of tian formed the basis of the principle of *tianming*, or the Heav-

enly Mandate, that gave human subjects tacit permission to overthrow morally corrupt rule. The desire to use heaven in determining the proper course of human action drove the Chinese to develop continuously more refined systems of predicting heavenly regularities and especially irregularities. For example, the oldest known system of Chinese divination reads cracks resulting from the application of heat to a prepared oxen scapula bone or tortoise shell (scapulimancy and plastronomy, respectively). These oracle bones record the rudiments of the stem-branch calendrical system. Later, diviners discerned heaven's will (not to be confused with Christian notions of heaven) by constructing combinations of six lines using numbers generated by manipulating yarrow stalks. Rituals developed around these prognostications for most major undertakings: initiating war, the birth of royal progeny, choosing new rulers, and so forth.

Tianwen were the source of civilization, a belief originating in the *Book of Change* (*Yijing*), a revered manual of divination and governance: the mythical sage-ruler Fu Xi looked up and saw the patterns of heaven, looked down and observed the markings of nature, and then modeled human affairs on both. This moment initiated Chinese civilization. The belief in heaven as the source of all power was developed and refined through the millennia of Chinese history. Theories of cosmology with heaven as the source of life and power-giving forces—*yin-yang* (shadow and light, basic complementary life forces), *qi* (universal essence); five phases (phases of change and composition; fire, water, earth, metal, wood)—and the way they could be tapped by humans developed along with philosophical theories of the reciprocal moral resonances between heaven, earth, and human (*ganying*). Some incipient form of all of these likely developed before the imperial era began in 220 BCE. These ideas, along with the Mandate of Heaven, would endure as fundamental ideas throughout imperial China (220 BCE–1911 CE), at least.

By the third century CE, the imperial system of governance, already highly bureaucratized, designated one of its highest offices to the grand astronomer, the head of a bureau of variously ranked experts who specialized in reading and interpreting the heavens and observing and pre-

dicting eclipses, comets, meteor showers, sunspot activity, and other astrological anomalies. This office also generated calendars, a new system of timekeeping usually formally issued with each new reigning emperor. Such experts also generated the Tianwen chapter of the official history for the previous dynasty. This chapter described the constellations, their locations, and astrological anomalies: it took position at the beginning of the official history, attesting to its importance to imperial rule. Originally the grand astrologer headed the entire history-writing project for the dynasty, Sima Qian (145–ca. 85 BCE) being the first and most famous of these.

Competing theories of cosmology—the universe and how it was constructed—became increasingly synthetic through history and deeply influenced Chinese philosophy. The developments of the Tang (618–907) and Song (960–1279) dynasties stand out as a watershed in changing cosmic views. The first change revolves around the idea of *xiang* (constellation, image, symbol, simulacrum, doppelganger, other-identity). In the transition from the Tang to the Song, the conceptualization of *xiang* and its place in cosmology and philosophy deepened. Song philosopher Zhou Dunyi (1017–1073) visually described cosmological forces—the relationship of *yin-yang* to *qi*—shown in the now well-recognized *taiji* diagram. Important changes accompanied his theories: the idea of *xiang* as constellation descended from the heavens and into the human realm as images and symbolizations. These heavenly related images (*xiang*) manifest in concrete things: clouds, certain birds (cranes, for instance, as depicted in Song emperor Huizong's [r. 1100–1125] famous painting *Cranes over Kaifeng*), anomalous animals (traditionally auspicious or inauspicious omens), weather patterns, and so forth. Therefore, earthly phenomena contained and embodied some aspect of heavenly constellations. Polymath Shao Yong (1011–1077) further refined the nature of cosmic forces, developing a theory of four orders of reality—*li* (patterns, principle), *shu* ([heavenly] regularities and also number, category, emblem), *xiang* (images, symbolizations; “constellations” of the Tang), and *wu* (concrete things)—that ultimately connected concrete things (*wu*) to heavenly principles and patterns

(*li*). This vastly expanded the potential for human manipulation of the heavens, and many systems for expressing and taking advantage of the power of heaven through *xiang*, as simulacra, developed.

Given this kind of power, applications to many fields developed: medicine and alchemy, through meditation techniques and treatments that internalized and correlated cosmic models with the organs and various biological systems of the human body; art, especially painting (the Song is particularly known for the era during which painting became an acceptable elite practice); calendrical science; changed concepts of deities and asterisms in Buddhism, Daoism, and popular religion; and military techniques. Because of the geopolitical situation during the Northern Song dynasty (960–1125) at least, the court actively sought experts in the latter field. Cosmography rituals—especially those used exclusively by the military—exploited the gaps in calendrical time and maneuvered *xiang* as simulacrum of heaven to concentrate and direct power. In this system, the Chinese calendar system played a role. The Chinese use a sexagenary time cycle—that is, a 60-year cycle—tracked by means of using Ten Heavenly Stems correlated with Twelve Earthly Branches but nevertheless yielding a 60-year (six decades) rather than a 120-year cycle. The Stem and Branch system was also used, either individually or jointly, to track hours, days, weeks, and months. Each individual therefore has “eight characters” (*bazi*), used today in some Chinese communities to determine dates for christenings, weddings, breaking ground for building, and so forth. Cosmography rituals took advantage of the unused branches—there were two in each decade—and through applying a rather complicated set of operations using a compasslike device called a cosmograph jumped time or space, conjured weather, fogged the enemy, etc., useful indeed for troops surrounded by the enemy.

Early Medieval Indian Astronomy and Astrology

The achievements of Indian astronomers and astrologers in the early medieval period are truly fascinating and have proved to be of considerable importance in the subsequent development of mathematics. With references to astronomy in Indian sources dating back to as early as 2000 BCE in the Rig-Veda, the early medieval astronomers and astrologers of the subcontinent were the product of a rich ancient tradition that flourished after the conquest of Alexander the Great in the fourth century BCE. After this time a number of Indian astronomers based their calculations

on Greek epicycle theory. It was from this heritage that India became a center of astronomical and mathematical excellence between 300 and 1000 CE.

By the sixth century CE astronomy had developed into an integral part of Indian society, due in large part to the work of Aryabhata I (476–550 CE). Heavily influenced by Jaina mathematics, Aryabhata's work was the catalyst for new developments in Indian astronomy and mathematics. In his magnum opus, *Aryabhatiya* (498 CE), he proposed a heliocentric model of the universe. He used a mathematical system to suggest that the earth spins on its axis and that the planets follow an elliptical orbit around the sun. He stated that the light from the moon and the planets was reflected by the sun's rays.

Aryabhata is the first known astronomer on the Asian continent to have used a continuous system of counting solar days, and he made an accurate approximation of the earth's circumference and diameter. He also correctly deduced the instantaneous motion of the moon and established numerical and geometric rules for eclipse calculations. Aryabhata's calculations of the sidereal rotation of the earth and its rotations in comparison to lunar orbits are precise and very similar to today's values.

His astronomical calculations were also reliable for fixing the Panchanga (Hindu calendar), thus showing the integration with Hindu cosmology. Whereas *Aryabhatiya* mainly influenced southern Indians, Aryabhata's second work, *Aryabhatasiddhanta*, greatly influenced northwestern India and has been mentioned by various scholars. It is also known to have had some influence on Sassanian and Islamic astronomy.

In the sixth century CE the school of mathematics at the ancient city of Ujjain came to prominence due to the work of astrologer Varahamihira (505–587 CE). In *Pancasiddhantika* (575 CE) he brought together the five systems of astronomy existing in this period: Suryasiddhanta, Romakasiddhanta, Paulisasiddhanta, Vasishtasiddhanta, and Paitamahasiddhanta. Also based in Ujjain, the astronomer and mathematician Brahmagupta (598–668 CE) defined zero as the result of subtracting a number from itself and was the earliest astronomer to use algebra to solve astronomical problems. He also developed methods for calculations

➤ ASTRONOMICAL EDUCATION IN INDIA

Between 300 to 1000 CE, the educational system in India did not offer proper training for those specializing in astronomy, astrology, and mathematics. Disciplines such as astronomy and mathematics developed autonomously, separate from the development of other areas of knowledge, and as a result most people interested in these subjects were family educated. Each family would have a library where they would then pass on their knowledge and skills to future generations. As the main part of study involved learning the work of previous generations including, for example, Aryabhatiya, astronomers would often write commentaries on previous astronomers' work and also on their own work.

—Polly Basak

lating the motion and location of various planets, conjunctions, and eclipses and the values of sines.

During the first half of the seventh century the Indian mathematician Bhaskara I (600–680 CE) prospered in Saurashtra, where he led the Asmaka school. He completed three papers on the works of Aryabhata: the *Mahabbhaskariya*, the *Laghubhaskariya*, and the *Aryabhatiyabhasya*. In all his works Bhaskara I expanded on the complicated and aphoristic style of Aryabhata's astronomy and added various examples and references including detailed mathematical procedures. He estimated the trigonometric sine function by means of a rational fraction and produced accurate and clear results. It is thought that Bhaskara I was the first to write numbers in the Hindu-Arabic decimal system, where he used a circle depicting zero.

The next major advancements in Indian astronomy were made in the ninth century by the mathematician Govindasvamin (800–860 CE) who wrote *Bhasya* (830 CE), a commentary on the *Mahabbhaskariya* of Bhaskara I. *Bhasya* included a place-value Sanskrit system and construction of a sine table. Govindasvamin calculated fractional parts of Aryabhata's tabular sine differences and in doing so produced more accurate results. Three of Govindasvamin's works, *Govindakrti* on astronomy, *Govindapaddhati* on astrology, and *Ganitamukha* on mathematics, are known only from references and quotations by later writers including Sankaranarayana (869 AD) and Udayadivakara (1073 AD).

The ninth century also saw mathematical progress from Mahavira, Prthudakasvami, Sankara, and Sridhara in terms of developing sine tables, solving equations, and indeterminate equations. Aryabhata II and Vijayanandi excelled in the tenth century by adding to the understanding of sine tables and trigonometry, but it was not until the twelfth century that Bhaskara II provided a unique and summarized study of astronomy and mathematics for that time. His work on calculus, astronomy, and the number of systems marked the culmination of a rich period in Indian astronomy that would not be equaled anywhere in the world for several centuries. By the time Nicolaus Copernicus printed his *De revolutionibus orbium coelestium* in 1543, Latin translations of Aryabhata's *Aryabhatiya*

had been available for more than two centuries (and Arabic translations since the eighth century), so it is almost certain that Copernicus' ideas were influenced by Aryabhata's work.

Early Muslim Astrology

As with so many of the intellectual pursuits that attracted Arabic scholars, Arabic astrology devolved from Greek philosophy though with a healthy leavening of Indian influences. Excited by the intellectual achievements of the Indians, either Ibrahim al-Fazari or his son Muhammad translated the *Sindhind*, which was itself based upon Alexandrian Greek learning. This text immediately catalyzed interest in the celestial sciences, but as a theoretical treatise on astronomy and mathematics it offered little practical application. For this reason, scholars soon applied themselves to a translation of Ptolemy's *Almagest*. Arabic scholars found themselves drawn to this work because their interest in Greek learning was directed primarily at the practical arts rather than the purely theoretical or aesthetic. The *Almagest* coupled with Euclid's *Elements*—another text translated in the ninth century—provided the basis for applied predictive astronomy, or what would come to be known as astrology.

Despite this broadly held utilitarian approach among Arabic intellectuals, religious officials soon directed their ire at astrology. This is typified by the anonymous charge directed at the ninth-century astrological authority, Abu' Ma'shar, that he had "studied astrology until he became an atheist." The primary reason for this opposition was the concern that a system of knowledge promising to predict the future

► ALBUMASAR

Abu Ma' shar Ja'far bin Muhammad al-Balkhi, known to the West as Albumasar, was the most important scholar of astrology in the Arabic East. He was born in Khurasan in 787 and died in Iraq in 886, and his reputation was never as high in his homeland as it would become in the Latin West. He saw astrology as the preeminent form of natural philosophy, with fields such as medicine simply applying its principles in a narrowly utilitarian fashion. Promoting this view in compendia of astrological axioms intended as practical manuals, these became standard for practicing astrologers in both Muslim and Christian lands.

—Scott Hendrix

would negate man's free will. Before the rise of the Asharite school of theology in the tenth and eleventh centuries, Muslim theologians generally considered free will to be an axiom of their faith. Even with the peak of Asharite influence, seen in the work of the eleventh-century Sufi al-Ghazālī, the idea that the stars might mediate God's influence was distasteful to many religious scholars.

Nonetheless, interest in astrology remained high. The sophisticated intellectuals of the Arabic world found its model of a universe of inter-related bodies interacting with one another in a thoroughly logical and predictable fashion to be eminently appealing. Furthermore, political elites found the promise of astrological guidance to be too attractive to pass up, and soon astrologers could be found at almost every court. Most famously, the caliph al-Mansur planned the laying of the first stone for the city of Baghdad in 762 around the casting of an astrological election, meant to determine the most propitious time for an action, by the Persian Jew Masha'allah.

These early scholars did not greatly differentiate between astrology and astronomy because their Greek sources presented the two as components of a single science. But opponents of the predictive aspect of this science provoked a creative institutional response in the eleventh century. Soon mosques began hiring men skilled in astronomy to fill the new position of *muwaqqit*, or time keeper, in order to maintain the calendar. However, any association with predic-

tive astrology would represent a bar to this position and its guaranteed income.

Soon, beyond a lucky few with secular positions, astrologers were pushed into the streets. Eventually this led to a division in the science once known as *'ilm al-nujum*, or the science of the stars, into *'ilm 'abkam al-nujum* (the science of the decrees of the stars—astrology) and *'ilm al-hay'a* (the science of the [heavenly] configurations). This split, based on religious and social pressures in the Arabic world, would have enormous impact, as the component parts of Ptolemy's astronomical science would eventually be transferred as separate bodies of knowledge to European scholars in the Middle Ages.

This conceptual distinction fundamentally altered the way in which scholars understood the heavens. Buttressed by Abu Ma'shar's ninth-century philosophical justifications for predictive astrology within a monotheistic culture and the mathematical developments of his near contemporary Thabit ibn Qurrah, astrology persisted as a discipline in the Arabic world well into the modern era, influential in many courts though ever suspected in mosques. It was this celestial science—seen as related to but not conjoined with astronomy—that would be passed to the West beginning in the twelfth century.

Islamic Astronomy to 1000 CE

Early Islamic astronomy, although often the product of Persians, Syrians, and astronomers of other ethnicities, is known as Arabic astronomy, as Arabic was the lingua franca used by Muslim scholars. From the eighth to the fourteenth centuries CE, Arabic astronomy was the most ad-

vanced in the world, only rivaled (perhaps) by that of the Mayas before the collapse of their civilization in the ninth century.

Arabic astronomy grew out of a synthesis of Hellenistic Greco-Roman astronomical lore, Persian astronomical tables, and Indian astronomy, all of which are indebted to Babylonian astronomers of the first millennium BCE. Important immediate sources of Arabic astronomy were three works: Ptolemy's *Almagest*, a Greco-Roman compendium of Babylonian, Persian, and Greek astronomical tables; Bhramagupta's *Surya Siddhanta*, a compendium of Indian astronomy (written in 628 and translated from Sanskrit into Arabic [777] as *Zij al-Sindhind*); and the *Zij al-Shab*, Persian astronomical tables compiled during the Sassanian era.

The first pressing impetus for astronomical research was religious: the Muslims conducted their holy year according to a lunar calendar based on the sighting of the crescent new moon. Because of the vast expanse of the Muslim conquests, the Muslims needed a system of predicting the appearance of the crescent new moon so that the calendar would be uniform throughout the Muslim dominions. Eventually, Muslim astronomers discovered a system of prediction by using the sine function of spherical trigonometry developed by the Indians rather than the more cumbersome geometric chord system advocated by the Ptolemaic *Almagest*.

Another religious stimulus was the need to know the direction of the Holy City of Mecca, the focus of Muslim prayer. In the far-flung Islamic empire, determining the direction (the *qibla*) in which Muslims should pray became a problem that occupied the interest of many Arabic astronomers. One solution of these Arabic scientists employed an instrument similar to a sundial. At the two days in the year when the sun is directly overhead in Mecca, a shadow will point in the direction exactly opposite from that of Mecca in any place where the sun is shining. This system works only in the half of the globe that shares daylight with Mecca.

Starting in the mid-eighth century, a great flowering of Arabic astronomy took place. Abbasid caliph al-Mamun (r. 813–833) supported the acquisition of scientific knowledge, especially the translation of scientific works from

Greek, Persian, and Sanskrit, by establishing the *Bayt al-Hikma*, said to have been a translation bureau as well as a research center. It is said that on one occasion he refused to sign a peace treaty with the Byzantine empire until the Byzantines delivered to him a copy of Ptolemy's *Almagest*. Al-Mamun is also said to have sponsored astronomical campaigns near Baghdad to determine the length of a degree of latitude. In the tenth century, several Muslim rulers as well as a number of wealthy private individuals established observatories to determine latitude and to study the stars and planets.

The achievements of Arabic astronomy are considerable. Many of the English words dealing with astronomy, such as "azimuth" and "zenith," derive from Arabic.

Arabic astronomers devised or improved many astronomical instruments, such as the armillary sphere, the astrolabe, and the celestial globe. Muslim astronomers, like the Indians and Greeks before them, calculated the circumference of the earth with some accuracy. And some Arabic scientists, such as Jafar ibn Muhammad Abu Mashar, devised a sun-centered theory of planetary motion (as had some Indian savants before him), thus anticipating Copernicus by more than half a millennium. However, most Arabic astronomers, like their European counterparts, clung to the Ptolemaic geocentric model of planetary motion.

A roll call of the great Arabic astronomers would include many who were also accomplished in mathematics, geography, history, medicine, and alchemy.

Al Khwarizimi (ca. 830) was one of the early synthesizers of Hellenistic and Indian scientific traditions with his work *Zij al Sindb*. Al Farghani (ca. 850) discussed Ptolemy's *Almagest* but revised some of Ptolemy's calculations. Also in the ninth century, Abi Mansur subjected Ptolemy's work to careful tests and modified them considerably in *Al Zij al Mumtaban*. The tenth century witnessed a large amount of astronomical observation and description. Al Sufi wrote about the Andromeda Galaxy and the Magellanic Cloud. Ibn Yunis did important work on the description of the sun and the prediction of eclipses. And al Khujandi correctly calculated the tilt of the earth's axis.

From the eleventh to the fourteenth centuries, Arabic astronomy experienced its golden age. Arabic astronomy influenced Indian and Chinese astronomy; in Europe it laid the groundwork for a great upsurge of astronomical achievement after the fourteenth century.

India's Golden Age of Mathematics

During the period 300–1000 CE, India was central to the development and diffusion of mathematical learning. Indian mathematics, which had ancient underpinnings in Vedic and later Jainist thought and likely cross-fertilization from Greek, Mesopotamian, and Chinese learning, underwent its own renaissance in the Classical Period. During the Gupta dynasty (320–550) in northern India, trade, the arts, and learning flourished. Toward the end of this longer period in the eighth century CE, the Muslim world, through conquest and trade, was first introduced to Indian mathematics, including the notation system since termed “Arabic numerals” and adapted it as the universal standard. A flourishing of Indian mathematics developed with the career of the astronomer Aryabhata the Elder (ca. 476–499) and the subsequent astronomers Varahamihira (ca. 505–587) and Bhaskara (ca. 600). Other key figures in Indian math in the latter half of the first millennium include Brahmagupta (b. 598), Mahavira (ca. 850), Sridhara (ca. 900), and Aryabhata II (tenth century). The culmination of this tradition was Bhaskara (ca. 1104) from Mysore who headed the astronomical observatory in Ujjain.

The study of mathematics in India was closely related to religion and cosmology. In ancient India, the study of math was related to the construction of precise altars in wealthy homes and temples. The *sulvasutras* that codified such

information date to as early as 800 to 500 BCE and provided numerous geometric principles. In order to describe vast stretches of time related to Hindu cosmology, that is the four *yugas* that can refer to cycles of years as large as 1.728 million and total only one-thousandth of the larger time cycle known as a *kalpa*, such texts as the *Upanishads* meditatively explored very large numbers and their theory. During the Gupta dynasty, there was a revival of Sanskrit thought and interest in the astronomical texts known as the *siddhantas*. Mathematical study closely dovetailed with astronomical observations and interest in astrology and methods for accurately casting horoscopes.

The works of astronomer Aryabhata I, who lived in the Gupta capital of Pataliputra, were enormously influential. Aryabhata systemized the thought to be found in the *siddhantas* or astronomical texts of earlier centuries. Arguably, much of the mathematical thought presented in the *siddhantas* came to India by way of Greece. One surviving example, the *Surya Siddhantas* (“System of the Sun”) of circa 400 CE and attributed to Surya, the Sun god, presented its theories of astronomy in verse and included mathematical notation that employed ciphers to represent ten numerals. Published at the end of the fourth century, Aryabhata’s central work, the *Aryabhatiya*, also was written in verse and employed a system of 33 letters to represent numbers, in base ten. Drawing from *siddhantas* such as the *Surya Siddhanta* and the *Paulita Siddhanta*, it was divided into sections named *Ganita* (arithmetic), *Kala Kriya*, and *Gola* (both of which treated astronomy, particularly the position of the planets and related calculations). The *Aryabhatiya* included rules for arithmetic and trigonometry, a table of sines, a calculation of pi of 3.1416, algebraic methods for solving quadratic equations, and an analysis of simple indeterminate equations (with one or more unknowns, generating answers in sets).

Mathematical thought continued to flourish with the work of subsequent Indian astronomers such as Varahamihira and Brahmagupta. Varahamihira’s *Pancasiddhantika* (*Five Astronomical Canons*) served as a guide for casting horoscopes based on astronomical calculations; this work included references to the use of the con-

cept of zero and principles of trigonometry. Brahmagupta's *Brahma Sphuta Siddhanta* (*Opening of the Universe*) included the chapter "Kuttaka," or the "pulverizer" (algebra), that elaborated on Aryabhata and included further methods for solving indeterminate equations.

The origins of the concept, notation, and nomenclature of zero are debatable. In Mesopotamia, the Sumerians early on developed cuneiform symbols that the Babylonians later adopted into a place-value system that eventually included an additional cuneiform symbol to indicate a lack of a number in a place value. This was a long process of adaptation, but it was certainly in common use by the eighth century BCE. Although sometimes credited with hatching the zero, Greek geometers did not rely on a system that clearly demarcated place value or zero; however, Greek astronomers of the Hellenistic era did (the concept almost certainly transmitted following Alexander's campaigns in the Near East), and the symbol for zero can be found in Ptolemy's *Almagest*. The zero was independently invented among the Maya as well in about the fourth century CE. The zero surfaced again in India, and by the time of Brahmagupta, in the seventh century CE, the symbol for zero, or *sunya* ("void"), was in use along with place-value specific notation. Some have attributed its adoption to his works, although its pedigree in India may well have stretched back several centuries. And it was from India that the concept dispersed to Arabic learning (where it was called *ifr* ["nothing"]) and later European thought (*zefiro* in Italian).

By the time of Brahmagupta, Indian astronomy and mathematics had gained high regard; translations of Indian works on mathematics and astronomy into Chinese began in about 600 CE, which is also when Indian astronomers were invited to teach in Chang'an in China. Indian mathematics also had a strong impact to its west. The Syrian scholar Severus Sebokht (fl. 660) described with appreciation the accomplishments of Hindu learning and its number system. By the last centuries of the first millennium, while mathematics continued to flourish in India, the center of such thought shifted to Muslim world thinkers such as al-Fazari the Elder, who served at the Abbasid court in Baghdad of Caliph Harun al-Rashid, and al-Khwarizmi, who joined the

WORD PROBLEMS IN BHASKARACHARYA'S *LILAVATI*

Bhaskara II (b. 1114), also called Bhaskaracharya, was a mathematician and astronomer in Ujjain, India, and the author of numerous works that were translated and made available interregionally. Centuries later, for example, the *Lilavati*, from which the word problem below is excerpted, was translated into Persian for the Mughal ruler Akbar. As this colorfully worded selection indicates, mathematical word problems not only have a lengthy pedigree but also take on the flavors of the cultures that produce them. The solution requires calculations involving square roots (the answer, by the way, is 72):

"From a swarm of bees, a number equal to the square root of half the total number of bees flew out to the lotus flowers. Soon after, $\frac{8}{9}$ of the total swarm went to the same place. A male bee enticed by the fragrance of the lotus flew into it. But when it was inside the night fell, the lotus closed and the bee was caught inside. To its buzz, its consort responded anxiously from outside. O my beloved! How many bees are there in the swarm?"

academy established by the later caliph al-Mamun (r. 813–833). Among his accomplishments, al-Fazari is said to have translated in 773 a set of Sanskrit astronomical tables into Arabic that introduced the Hindu numerals. Al-Khwarizmi in 825 wrote a short treatise explaining the value of the Hindu numeral system that was later translated into Latin. Such thinkers were able to synthesize and elaborate upon works from India and Greece as well as Latin and Byzantine sources.

Early Medieval Mesoamerican Mathematics

The peoples of Mesoamerica developed sophisticated mathematical systems prior to contact with the Europeans. Their system was based upon 20, with different symbols representing multiples of 20. Mathematics played a key role in the creation of calendars and the tracking of celestial bodies

Mayan numbers consisted of three different symbols: a shell (representing zero), a dot (one), and a line (five). Numbers greater than 20 were represented by symbols placed above the symbols representing "ones," just as numbers greater than 10 are represented by symbols placed to the left of the "ones" in Western mathematics. Although odd-looking by modern Western standards, the system worked very well.

by the Maya and the Aztecs as well as in the building of their cities. Native American mathematicians also developed the concept of zero sometime around the year 300 CE before it made its appearance in European mathematics.

The Maya are generally credited with inventing a system of mathematics that was used throughout Mesoamerica before the Spanish conquest. Unlike the European system, which was based on 10, the Mayan system was based upon 20. It probably originated because both fingers and toes were used for counting. The Mayan system was used by later civilizations, such as the Aztecs. Subsets of 5 were used as well. In the Mayan language, words for numbers larger than 5, such as 6, could be translated as "5 plus 1." A single dot represented 1, while a bar represented 5. Three bars and 4 dots represented 19, and a symbol resembling a flag indicated 20. Symbols representing larger numbers were based on powers of 20. Twenty squared, or 400, was indicated by a feather. A glyph of a bag of copal incense represented 20 to the third power, or 8,000. Mayan mathematicians also developed a system of anthropomorphic figures to represent some numbers as well as nonnumerical symbols to give numbers more aesthetic appeal.

One of the greatest inventions of Mesoamerican mathematicians was the development of the concept of zero. Zero made its appearance in Mesoamerica before the Hindi or Muslim scholars developed it. Mayan monuments dated to 665 CE use symbols for zero. Earlier inscriptions, from at least 357 CE, appear to use the concept as well. Coincidentally, mathematicians in India were using zero as a number and as a place holder by 500 CE.

Mayan mathematicians also developed the use of positional notation in their numbers. Unlike Arabic numbers, which use a left to right arrangement, Mesoamerican mathematicians used a vertical arrangement. The location of a symbol for a number in the stack determined what the actual value of the number was, that is, ones, tens, hundreds, etc.

A sophisticated numerical system allowed the medieval Mesoamericans to gain a more secure grasp of their world. One of the most famous uses of mathematics was the development of accurate calendars. Two separate calendars

were in use, both based on the base 20 mathematical system. One was a ritual calendar of 260 days consisting of 13 months of 20 days each. Modern scholars point out that 260 days is the average length of time that humans are carried in their mother's uterus. The second was a year of 365 days, divided into 18 20-day months with 5 extra days at the end. The Mayans in particular accurately calculated the length of a year and the time of the moon's cycles. Mathematics made accurate observations of the objects in the heavens possible along with accurate predictions of their future movements. Thanks to observations and mathematics, Mayans were able to predict the times in which eclipses might occur, making it possible to prepare the population for those unsettling events.

Mathematics was also used in the organizing of society, ensuring accurate taxation and recording of landholdings. A common measurement called the *quahuil* was used throughout Mesoamerica. It measured approximately 8.2 feet (2.5 meters). Tax rolls were compiled by the authorities to indicate what was expected of different communities. The sizes of different agricultural plots were spelled out on the rolls, indicating the square number of *quahuil* that each included. Lists of tribute expected from subject communities have also survived, indicating the numbers and types of items that were to be supplied to the central government.

Archaeological evidence indicates that medieval Mesoamericans used geometry in construction. Elements such as right angles, symmetry in site layout, and the use of other regular angles all indicate that geometric principles were known to Mesoamerican architects. Even the basic view of the world by the Maya was based on geometric concepts. They believed in harmonizing with the four cardinal directions of north, east, south, and west and used right angles that followed these directions in constructing their cities.

Mathematics in the Muslim World to the Year 1000 CE

The Muslims emerged from Arabia in 636 CE with nearly no high culture of their own, including mathematical knowledge. In light of that deficiency, the zenith reached by mathematicians in the medieval Islamic world is nothing short of amazing, as they introduced to the Mediterranean world fundamental changes including a new arithmetical notation and developed new methods of solving mathematical problems.

The mathematical sciences (*‘ilm al-‘adad*) in the Muslim world developed primarily as an extension and expansion of Greek and Indian mathematics. The Hellenistic tradition had delineated four mathematical sciences—arithmetic, geometry, music, and astronomy—and Islamic scholars excelled in each of these sciences. The major accomplishment of mathematics scholars was bringing together different elements from Greek, Persian, and Indian roots and then combining these ideas into a more sophisticated science. This accomplishment was made possible by the translation in Abbasid Baghdad of Greek mathematical works such as Euclid's *The Elements*, Archimedes's *On the Sphere and the Cylinder*, and even commentaries upon these works, such as Eutocius's *Commentaries on "The Sphere and the Cylinder."* Such works were collected in libraries throughout the ninth century CE and were discussed in scholarly symposia known as *majlis*.

While there were some earlier scholars in the field, the most famous of all was Abu Jafar Muhammad ibn Musa al-Khwarizmi, who is remembered as the founder of algebra and as the man who introduced the Indo-Arabic numbers to the Islamic world. He wrote for the Abbasid caliph al-Mamun (813–833 CE) and was an active member of that circle of translators and scholars in ninth-century Baghdad, sometimes referred to

as the Bayt al-hikma (House of Wisdom). Al-Khwarizmi wrote his most famous text, *Handbook for Calculation by Completing and Calancing* (in Arabic, *Kitab al-mukhtasar fi hisab al-jabr wa'l-muqabala*), to fulfill a request of the caliph for practical works on this science. The book demonstrates two main processes for solving equations. While he may have found both methods in Diophantus's *Arithmetic* and probably derived some of his terminology from Indian mathematical practice, it was al-Khwarizmi who brought these elements together. Theoretically, he shows that equations can be reduced to one of six standard forms. The remainder of the book deals with the practical applications to problems of inheritance, trade, legacies, and various kinds of geometrical problems. Confusing and ironic as it may be, al-Khwarizmi did not use any kind of numerical symbols or algebraic notation; all problems were discussed in words. This work became the foundational text of algebra even within his lifetime. The Ikwan al-Safa' (tenth century CE) in their encyclopedic *Letters (Rasa'il)* use *al-jabriyyun* as the term for the scholars who know this subject.

Equally important, al-Khwarizmi wrote a small work titled *Calculation with Hindu Numerals*. Before his time, Muslims had used an alphabetical number system, as the Greeks had. Like the *Algebra*, this was the first work of its kind in Arabic treating the Hindu numbers including zero and place-value notation. It teaches the use of the numerals, the basic arithmetic operations, fractions, and the extraction of square

roots. Perhaps because it was such an elementary text, this work was initially of limited consequence in the Arabic-speaking world, and the Arabic original has not survived.

Scholars who came after al-Khwarizmi continued to advance the science, taking up problems that the Greeks had left unsolved. Ibn al-Baghdadi (first half of the tenth century CE) discussed the theory of irrational numbers, a conceptual advance beyond Greek knowledge. Abu Kamil Shuja (ca. 850–956 CE) solved systems of equations in up to five unknowns. Ibn al-Haythan solved fourth- and fifth-degree equations, even lending his name to one particularly vexing solution, the so-called problem of Alhazen. It was the contribution of the great Umar Khayyam (ca. 1038–1123 CE) to summarize and systematize the development of algebra up to his time by establishing standard terminology and categorizing the solutions to classes of equations.

The importance of Arabic mathematics is seen in the development of the contemporary sciences of astronomy and geometry. Calculations were made simpler by the use of Arabic numbers, especially zero, and recording of data was greatly improved by reducing confusion inherent in an alphabetical notation system. This development was seminal in world history.

■ Introduction: Early Medieval History and Geography

The Chinese wrote the best histories in the early medieval age. Each succeeding Chinese dynasty regarded the writing of history as a political, cultural, and religious duty and appointed official historians whose task was to write the history of the preceding dynasty. This practice produced an unbroken stream of history writing, but it sometimes produced very

biased histories. For example, the historians of the Tang dynasty who were charged with compiling the history of the Sui, in order to justify the Tang takeover, left posterity with the view of the two Sui sovereigns as two monstrous tyrants. By the middle of the Tang dynasty, history began to be seen as not just a genre of literature but also as a special discipline with its own goals and

rules. Liu Chih-chi (Wade-Giles) published the world's first study of historiography (ca. 700 CE). At the end of this era, Sima Kuang (1018–1086) produced a second historiographical study of China's histories.

Many modern historians charge that the civilization of India was not oriented to history and that the Indians had little sense of history, particularly of precise chronology. The Puranas, which historians sometimes use as sources, were largely published in the Gupta Age but were mostly composed for oral transmission centuries before. Much of the material in the Puranas is probably based on facts, but it is so mixed with mythology that it creates great difficulties for the modern historian. Again, the chronology in the Puranas is, at best, very confusing and often lacking. Consequently, modern historians of early medieval India must rely heavily on Greek, Persian, Chinese, and Arabic accounts. In the early medieval age, the accounts of the Chinese Buddhist pilgrims to India, Faxian (334–420), Xuanzang (596–664), and Yijing (635–713), were often more informative than Indian sources. There are some exceptions including biographies of some important rulers, such as the seventh-century *Harshacharita* (*Biography of Harsha*) by Banabhatta.

The Byzantines had the benefit of the Roman and Hellenistic tradition of history writing, and they continued the tradition throughout the early medieval age. Byzantine historians focused on ecclesiastical history (indeed, many of their works are titled simply *Ecclesiastical History*), but they also usually compounded political history with that of the church. While the writing of history in Byzantium was not a government enterprise as it was in China, many individuals saw it as their duty to write the history of their age, building on the histories written by those who went before them. The most notable of these historians were the fourth-century Eusebius of Caesarea, whose *Ecclesiastical History* chronicles the triumph of Christianity in the Roman empire, and Procopius, who wrote about the reign of Justinian I and whose *Secret History* has blackened the reputation of that ruler for succeeding generations.

West European historians, like their Byzantine counterparts, were concerned with writing about saints' lives as didactic tools for the young. Nevertheless, some early medieval European his-

torians, such as the sixth-century Gregory of Tours (*History of the Franks*) and the ninth-century Venerable Bede (*Ecclesiastical History of the English People*) wrote valuable accounts of their nations.

Muslim historians were very good at writing about the history of the Islamic world, but they were less interested in pre-Islamic history, the period they referred to as the Age of Ignorance. Beginning in the eighth century CE, a growing stream of history writing by Islamic scholars appeared. Ibn Ishaq's *Life of God's Messenger* (*Sirat Rasul Allah*), published about 730 CE, was the first written biography of the Prophet Muhammad. This work was followed by a spate of works on the early history of Islam, concentrating especially on the early conquests. While in the early Muslim centuries Islamic historians were primarily concerned with telling the story of the triumph of Islam and the growth of the Muslim umma (community) in a world of nonbelievers, this disdain for non-Islamic history gave way to the developing interest, toward the latter years of the first millennium CE, in Firdusi's *Shahnameh* (*History of the Pre-Islamic Persian Kings*) and with the works of al-Biruni on India. Muslim historians were scrupulous in questioning their sources and in reporting what they regarded as fact, eschewing mythology.

Because of the vast expanse of the Islamic world and of the extensive trade carried on by Arabic merchants, Arabic geographers were the most informed in the world in the medieval age. This particular advance and development of geography was also due to the obligation of all Muslims, if they were able, to make a pilgrimage to Mecca. Muslim travel writers described much of the Eastern Hemisphere, from the West African Sudan to Korea.

Most peoples knew neither the shape nor size of the earth, although Hellenistic Greeks, the scientists of India, and Muslim astronomers accurately calculated this. Both the Chinese as well as the Muslims made maps by using longitude and latitude.

The Chinese were equally good as geographers as were the Muslims, but their field of interest was much more circumscribed. They just did not have the practical need for geographical knowledge that the Muslims did.

Besides the Muslims and the Chinese, the rest of the earth's peoples were ignorant of the geography of most of the earth. A partial exception must be made of the Eastern Polynesians, but their knowledge of the vast seascape of the Eastern Pacific, though astonishing, still included only a portion of the earth's surface, and it had the disadvantage of being transmitted by oral tradition, not written down. For the West Europeans, the horizons of their world were very constricted. However, their imaginations were fed by tales of fabulous voyages into the fearsome western ocean, tales that arose from the embellishment of reports of St. Brendan's sixth-century voyage into the North Atlantic.

—Wilfred J. Bisson

Early Muslim Geography

The Muslim study of geography was driven by the rapid conquest of vast territories, the religious need to determine the direction of Mecca for daily prayers, and the necessity of geographic knowledge in order to make the pilgrimage to Mecca (hajj) required of all Muslims capable of it. In addition to the requirement for geographical knowledge for governing the swiftly growing Islamic caliphate, the reinvigoration of old and extension of new trade routes, both by land and by sea, resulted in a veritable explosion of geographical knowledge.

A scant century after the emergence of Islam in Arabia, Muslims ruled territories stretching from Spain to India and from the Sahara Desert to the Siberian forests. Muslim merchants sailed the Mediterranean Sea, and they dominated the Indian Ocean. Their trading colonies settled in coastal towns from the west coast of India to Madagascar and the Swahili coast of East Africa. Thousands of Muslim merchants resided in the South China port of Canton; Muslim traders were settling in towns such as Kumbi Saleh in the West African savannah south of the Sahara Desert. The geographers and mapmakers of the Muslim world responded by organizing and ordering the resulting influx of geographic information.

Caliph al-Mamun (r. 813–833) commissioned a number of mapmakers to organize this wealth of geographical information, anticipating, in this

respect, the role of the fifteenth-century Portuguese statesman Henry the Navigator. Geographers employed by al-Mamun calculated the circumference of the earth at nearly the value arrived at by modern science. Musa al-Khwarizmi was the most outstanding geographer employed by the caliph. Al-Khwarizmi's great work, *Book on the Appearance of the Earth*, included much of the newly discovered geographic knowledge and corrected many of the mistakes in the work of Ptolemy, the great Hellenistic geographer.

Other great early Islamic mapmakers include Istakri, a Persian who in about 850 synthesized, in his *General Survey of Roads and Kingdoms*, most of the newly discovered geographic knowledge. He is said to have been the first Muslim to include Korea in his maps. Another great mapmaker, the early-tenth-century Persian al-Balkhi, started a tradition of extensive mapping that resulted in the production of world atlases. Ibn-Hawqal, who revised and extended Istakri's work, was a great tenth-century traveler as well as a geographical writer. His travels took him to most parts of the Muslim world, from Spain to the Upper Volga, and his great work, *The Face of the Earth*, is still consulted by scholars, especially for its descriptions of the Caucasus, pre-Christian Kiev, the Volga Bulgars, and Khazaria.

The culminating scientific achievement of early Muslim geography came at the end of the Era of Expanding Regional Civilizations in the early eleventh century with the work of al-Biruni. Al-Biruni, a Persian polymath who excelled in many fields, is known as the Father of Geodesy, the scientific measurement of the earth. For the earth's measurement, he used astronomy and spherical trigonometry and described the earth's surface by using a grid of latitudes and longitudes. In his famous work *The Chronology of the Ancient Nations*, he discussed human geography, agricultural systems, customs, and the like.

Thus, great strides in the accumulation of geographic knowledge and its scientific interpretation were made by early Islamic geographers.

Early Muslim History Writing

Islamic history was transmitted primarily by oral reciters until the latter part of the eighth century, almost a century and a half after the time of Muhammad. In the first centuries, Muslim historians did not concern themselves with pre-Islamic history, referring to that period as the “days of ignorance” (*jahalia*) and not worth studying. For them important history started with Muhammad, but the memory of Muhammad’s time was preserved only by word of mouth until Ibn Ishaq (704–761 CE) compiled, from oral sources, the first authoritative biography of Muhammad.

Likewise, the hadith, or traditions attributed to the Prophet, which are used in determining proper Islamic behavior as well as in legal judgments, were, until the ninth century, preserved by oral transmission. In the ninth century, authoritative collections of hadith were made, the most important of which were those of al-Bukhari and al-Muslim. In determining which hadiths were authentic, the hadith collectors developed a system of criticizing sources that has become the hallmark of the historical method. Basically, the hadith collectors demanded an *isnad* chain, a list of successive reporters going back to the source, who should be eyewitnesses of the event. For a credible hadith, an *isnad* chain should go back to Muhammad. Any or all of the reporters in the chain would then be examined for validity.

The writing of Islamic history is thought to have started with Ibn Munabbih when he published, in the early eighth century, *The Beginning (al-Mubtada)*. Although this is not considered reliable by later Muslim historians, it had a great influence on the field. The biography of Muhammad by Ibn Ishaq, which came out at about the same time, was said by the early-ninth-century historian Ibn Hisham to be definitive. Ibn Hisham, who is perhaps the best extant source on Muhammad (Ibn Ishaq’s biography of the Prophet survives only in renditions in Ibn Hisham’s work) was typical of the earliest Muslim historians, who concentrated on biographies of the Prophet and descriptions of his battles.

The next genre of Islamic history was that of collective biographies of early Muslim heroes and shaykhs: the Companions of the Prophet. Ibn Saad was outstanding among this group of historians, and his work, *The Great Book of Classes (Kitab al-tabaqat al-Kabir)*, includes over 4,000 biographies, of which 600 are of women.

Narrative histories describing events as well as individuals appeared in the ninth century. Eminent among these are Al-Baladhuri’s works *Kitab Futuh al-Buldan* and *Kitab ansab al-asbaf*. These are histories of the Islamic world from before Muhammad until the mid-eighth century. They are a chronological political narrative but also discuss society, trade and agriculture, ethnic groups, and the like.

The tenth-century Arab historian and geographer al-Masudi, sometimes referred to as the “Herodotus of the Arabs,” traveled through much of the Islamic world and wrote books on world history. The book that made his reputation as a major historian, *The Meadows of Gold and the Mines of Gems (Maruj adh-dhahab wa maadin al-jawahir)*, is al-Masudi’s own abridgement of his 30-volume work, *The History of Time (Akhbar az-zaman)*, which was a comprehensive history of the known world.

The writing of history by Muslim historians reached an apogee with the early-tenth-century Persian al-Tabari. Al-Tabari, writing in Arabic, produced important works of theology and Quranic exegesis as well as history. His major historical work is *History of the Prophets and Kings (Tarikh al-Rusul wa al-Muluk)*, better known in English as the *Annals of Tabari*. This was a universal history from the beginning of the world as depicted in the Quran to 915 CE. It is noted for its attention to detail and its rigorous assessment of sources. Modern historians consider it a reliable primary source for events of the ninth and early tenth centuries. Many scholars rate al-Tabari as the greatest Muslim historian before the fifteenth-century Ibn Khaldun.

East Asian Historical and Geographical Writing

Few other peoples were as historically minded as the Chinese. From a very early time, the compiling of history was seen as a fundamental task, and in this period Chinese governments took an increasing role in commissioning official historians or historical bureaus. The Han dynasty works Sima Qian's *Shiji* (*Historical Records*) and Ban Gu's *Han shu* (*History of the [Former] Han*) provided the model for all subsequent documentation of history. Succeeding dynasties recorded the history of their predecessors in standard histories. The *History of the Later Han* (*Hou Han shu*) by Fan Ye (398–445) represents the first such work, consisting of large sections copied from the *Han shu* and earlier (now lost) works on the Later Han. However, genuine innovation was not seen until the Tang dynasty. The Tang also provided the majority of historical work that survived from the period 300–1000 CE and oversaw an unprecedented bureaucratization in historical writing.

Most surviving histories covering the period from the fall of the Han to the Tang dynasty were produced by Tang scholars. At least 20 pre-Tang histories of the Jin dynasty were produced, but all were lost after Tang versions superseded them. Some were substantial works, such as Cang Rongxu's (415–488) *Jin shu* (*History of the Jin*), composed of 110 chapters. Surviving pre-Tang works include the *History of Song* (*Song shu*) by Shen Yue (441–513), officially commissioned by the king of Southern Qi, and the *History of Southern Qi* (*Nan Qi shu*), written by a relative of the king, Xiao Zixian (489–537). The *History of Wei* (*Wei shu*) was produced by a “research cluster” headed by Wei Shou (506–572). In their close connection to the ruling dynasty and given the group effort put into the *Wei shu*, these works anticipated future trends.

In 629 the Tang emperor Taizong established the Bureau of Historiography (*Shi Guan*). This department included scholars such as Wei Zheng (580–643) and Yan Shigu (581–645), who were assigned to produce historical works (presented to the throne from 636). The *History of Sui* (*Sui shu*) shows indications of political considerations in this period when the regime was anx-

ious to legitimize its rule (and blacken that of the Sui dynasty ruler Yang-di). Treatises were only included later, in 656. In addition to political concerns, the production team was also hampered by the loss of the Sui imperial library. Some works were lost during fighting in Luoyang, but most works were lost in 622 when boats transporting them to Chang'an capsized. Other commissioned works included the *History of Chen* (*Chen shu*), the *History of Liang* (*Liang shu*), the *History of the Northern Zhou* (*Zhou shu*), and the *History of Jin* (*Jin shu*).

The inevitable result of the bureaucratization of historiography was to standardize the works and eliminate the scope for literary expression. This can be advantageous for the modern historian, since it exaggerated the tendency toward the cut-and-paste technique, thus preserving source materials with less editorial interference. Efforts toward bureaucratization also systematized imperial record keeping with the compilation of Court Diaries and Administrative Records, to be written into *Veritable Records* (*Shi lu*) of an emperor's reign.

Government projects did not preclude private endeavors. Li Yanshou (fl. 618–676) produced two major works, the *History of the Southern Dynasties* (*Nan shi*) and the *History of the Northern Dynasties* (*Bei shi*). The impossibility of direct competition with the Bureau of Historiography may have provided an impetus for others to innovate. Liu Zhiji (661–721) published the *Comprehensive History* (*Shi Tong*) in 710, a work of historiographical criticism that broke from the constraints of dynastic history and traced issues to their ancient origins. His son Liu Zhi published a political encyclopedia called *Governmental Statutes* (*Zhengdian*) in 740 that in turn served as the model for the *Comprehensive Statutes* (*Tongdian*) by Du You (735–812). The *Tongdian* became the first of what are now called the *Ten Encyclopaedic Histories of Institutions* (*Shitong*). The topical divisions included economics, the examination system, the governmental system, rites, music, the military, law, administrative geography, and border defense.

Historiography after the Tang dynasty includes among its landmarks the *Old Standard History of the Tang* (*Jiu Tang shu*), which was written by Liu Xu (887–946), and the history of

the post-Tang age by Xue Juzheng (912–981) in the *Old Standard History of the Five Dynasties* (*Jiu Wudaishi*). Many of the best records for Tang and post-Tang chaos were produced during the Song dynasty after 1000 CE. The *Comprehensive Mirror on Human History* (*Zizhi tongjian*) by Sima Guang (1019–1086) used many lost sources and is thus also an invaluable resource for the study of pre-Song historiography.

From the Later Han dynasty, history had been classified as one of four branches of literature (*sibu*, identified by the color white in Tang imperial libraries), while geography (*dili*), along with annals, biographies, etc., was categorized as one of the subbranches of history. Standard works on geography included the *Shiji*'s memoirs on foreign peoples and lands as well as the *Han shu*'s chapter on administrative geography. These contained the data useful for officials, such as population figures and distance between places. Although various works specifically on geography were produced from the Han dynasty onward, few survive. It is only from the Song dynasty onward that a wealth of national and local gazetteers becomes available. The oldest surviving major geographical work is the *Gazetteer of the World during the Taiping Xingguo Reign Period* [976–983] (*Taiping huanyu ji*) by Yue Shi (930–1007), based largely on Tang dynasty sources. Travel writings, such as those by Li Ao (772–841), also provide geographical information.

The new East Asian states such as Silla (Korea) and Japan, which modeled their governments on that of Tang, also viewed history as a state responsibility. Their histories were on the model of Chinese dynastic histories, and they were written in Chinese characters. Japan produced its first historical works during the Nara period in the eighth century. The *Records of Ancient Matters* (*Kojiki*) and the *History of Japan* (*Nihon Shoki*) were both commissioned by the government and attempted to rationalize and synthesize traditional tales and myths. They were designed to create a respectable history in response to Tang dynasty influences. The *Records of Wind and Earth* (*Fudoki*), produced by provincial officials, described local conditions and traditions. Other regions of Asia did not produce works that can be properly classed as history or geography until after the eleventh

FROM BAMBOO STRIPS TO PAGINATED PAPER—THE EVOLUTION OF CHINESE BOOKMAKING

In the Han dynasty almost all documents were written on bamboo or wood strips. A knife for cutting and scraping them was as much a part of scholar's equipment as brush and ink. Even a modest-sized document would have been too heavy to lift, and a major work could fill a room. The strips were bound by string and if detached could easily get out of order. Silk was an alternative, but it was too expensive for regular use. Paper was already known but only became common in the third and fourth centuries CE, and the state of Chu was the first to institutionalize the use of paper when Emperor Huan Xuan decreed that it should be used instead of bamboo in 404 CE. Paper scrolls were lighter, but it was still inconvenient to consult different parts of a lengthy document. In the ninth century, scrolls were folded and stored flat and were attached at front and back to a single large sheet so that they could be opened concertina-like. Color coding in imperial libraries (white for history), previously done with strips of silk, was now replaced with different-colored covers. This form evolved into books with stitched binding by the thirteenth century.

Legends and Myths of Chinese Exploration

Chinese accounts of distant lands, in the same way as their Western counterparts, often included legends and myths. European sailors spoke of mythical islands in the Atlantic Ocean, and medieval cartographers placed imaginary

► THE CHINESE DISCOVERY OF AMERICA— THE VOYAGE OF FU SANG

Who was the first nonindigenous American to reach the Americas? Was it the Italian, Columbus? Or the Norse, Leif Erickson? Or perhaps the Chinese, Hui Shen?

An old Chinese legend speaks of a land called Fu Sang on the far side of the eastern ocean. One account states that a Buddhist monk named Hui Shen traveled in the fifth century CE to this land. This story is more than 1,000 years old, and various writers have claimed or denied that the place discussed in the tale is, in fact, America. The name “Fu Sang” appears on early Asian maps, with the mapmakers using information from the legend. In the legend itself, of course, the details are too vague to make any kind of positive identification. Because of the resilience of this legend, however, Fu Sang actually appears on the North American continent in some eighteenth-century European maps.

The story of Hui Shen is found in several Chinese accounts dating back to the seventh century CE. In these accounts several places are mentioned, and although none are readily identifiable, some have speculated that Hui Shen reached Mexico. The accounts tell us that Hui Shen and some companions headed east from China, across the seas, until they reached a coastline. They then traveled inland, exploring this new territory. They met various peoples, some of whom were fairly ordinary and some of whom were rather fantastic (for instance, men with dog-shaped heads). The group traveled farther, encountering a culture that had a written language and a form of government. Some have speculated that according to various Chinese texts, Hui Shen returned to China at the end of the fifth century CE and recounted his travels to the imperial court. The identity of the places he and his companions reached remains a mystery.

—Benjamin B. Olshin

peoples in the distant lands beyond the known world. In a similar way, the Chinese had their accounts of mythical kingdoms and people in the far reaches of the globe. Some traditions, in fact, are shared by both Eastern and Western sources. The Chinese in the Tang dynasty spoke of “kingdoms of women,” while the Greek historian Herodotus discussed the Amazons, a fierce nation of women warriors. There are similar shared accounts of dog-faced men, winged peoples, headless races, and so on.

A “kingdom of women” first appears in the *Classic of Mountains and Seas (Shan bai jing)*, a work that includes a great deal of imaginary geography. One passage of this text states that this kingdom is found “west beyond the seas,” and another says “west of the great beyond.” In most accounts of these kingdoms the women are said to reproduce without men. In some there are said to be no men at all, while in others there are men in a completely subservient role.

In the Chinese tradition, early maps include accurate geographical models, more fantastic schemes that include imaginary lands, and works that combine both. A classic example is a series of old circular Korean world maps based on Chinese prototypes. In these, China occupies the main area of the map in the form of a central continent, with Korea, Japan, India, and Southeast Asia nearby. The central continent is surrounded by an ocean, which contains many islands. Beyond this ocean there is another continent, completely imaginary; in turn, an all-encompassing ocean surrounds this second continent. In this final outer sea there are mythical islands to the west and east. The Japanese scholar Hiroshi Nakamura noted that many of the place-names on these maps come from the *Classic of Mountains and Seas*. Other place-names on the maps come from Chinese historical works such as the *Classic of History (Shu jing)*, the oldest of the Confucian classics, and the *Story of King Mu (Mu tian zi zhuan)*.

Chinese texts also speak of voyages to strange and wondrous places. The *Story of King Mu* includes some place-names that can be identified with actual locales, but there is also a great deal of material that is fantastic, such as the main character’s visit to the fabled “Queen Mother of the West.” According to Chinese leg-

end, Emperor Shi Huangdi (who reigned from 246 to 210 BCE) sent out the alchemist Xu Fu in search of an elixir of immortality. This elixir was said to be found in a place called Penglai, one of three islands where the immortals dwelled. Apparently there were a number of voyages sent out in search of herbs that could give longevity or immortality to the user.

One of the most famous Chinese legends of exploration concerns a place called Fu Sang, a land far across the seas to the east. Chinese texts dating back to the seventh century CE recount how a Buddhist monk named Hui Shen, originally from Afghanistan, traveled in the fifth century CE to Fu Sang. In the story, Hui Shen and some companions headed east from China, across the seas, until they reached a coastline. They then traveled inland, exploring this new territory. They met various peoples, some of whom are described in fairly ordinary terms and some of whom are rather peculiar, including a race of men with heads like those of dogs. The group traveled farther, encountering a culture that had a written language and a form of government. According to various Chinese texts, Hui Shen returned to China at the end of the fifth century CE and recounted his travels in the imperial court. The fact that no specific geographical details are given in the account gives it a particularly mythical and fantastic quality. Fu Sang is said to lie many thousands of miles beyond China. The account notes that Fu Sang is the name given to the land itself, and the term is said to be derived from the name of a kind of tree that grows there. The tree is described as supplying food, and its bark is said to be used for clothing. The term “Fu Sang” later came to be applied to Japan.

The story of Hui Shen’s travels appears in a book from the early seventh century CE titled *History of the Liang Dynasty* (*Liang shu*) by Yao Silian and in the later-seventh-century *History of the Southern Dynasties* (*Nan shi*), compiled by Li Yanshou. The *History of the Southern Dynasties* was copied and amended by the Chinese historian Ma Duanlin in his early-fourteenth-century *Comprehensive Studies in Literature* (*Wen xian tong kao*). This work, in a section titled “Investigation of the Four Frontiers,” recounts Hui Shen’s story. The story also appears in a slightly different form in the seventh-century

Memoir of the Four Gentleman of Liang (*Liang si gong ji*).

Ma Duanlin’s *Comprehensive Studies in Literature* speaks of a number of peculiar lands beyond China in the seas to the east. He, too, mentions a kingdom of women, to the east of the mythical Fu Sang, where the inhabitants become pregnant simply by entering a pool of water. In the same text a voyager lost in a storm at sea found an island by chance. Women who appeared to be Chinese but who spoke an unintelligible language inhabited this island. The men had human bodies with dog heads and voices that sounded like barking. These Chinese reports also spoke of a place beyond China called Wen Shen, which means “marked bodies,” perhaps referring to tattooing. Beyond this was a place called Da Han, or “Great China,” said to be abundant in sheep and horses. Early Chinese texts also speak of lands of giant men as well as pygmy races. Perhaps not surprisingly, these lands are frequently said to be in remote regions and are described in only the vaguest of terms.

Early Medieval Christian History

When Christianity became the official religion of the Roman empire under Constantine in 313, Christian historians began to integrate two very different kinds of history. Roman history centered around the Roman empire, while Christian history was structured around the sequence of events comprising God’s creation of the universe,

➤ EXCERPT FROM *THE CHRONICLE OF ST. JEROME*

“Indeed, if you do not falter in carefulness and when you have diligently pored over the Divine Scripture, from the birth of Abraham back to the Flood of the whole earth, you will find 942 years, and from the flood back to Adam, 2242, in which no completely Greek, or barbarian or, to speak in general terms, gentile history is found. That is why the present little work traces the later years from Abraham and Ninus down to our time; and starts by displaying Abraham of the Jews, Ninus and Semiramis of the Assyrians, because at this time Athens was not a city.”

—Shana Worthen

Source

Jerome, *The Chronicle of St. Jerome* (Jerome's Latin Translation of Eusebius' Chronicle), English translation by Roger Pearse. <http://www.tertullian.net/fathers/index.htm#jeromechronicle>.

the events of the Old Testament, the Crucifixion of Jesus Christ, and the forthcoming Last Judgment. Christian history had a preestablished end point. The earthly world would end with the Last Judgment, and only heaven and hell would remain thereafter.

Eusebius (d. ca. 339), Constantine's adviser, was one of the first Christian historians to unite Christian with Roman history. His *Chronicle*, written in Greek, was a world history from creation to his own time. He integrated the Old Testament with the histories of the Babylonians, Egyptians, and Greeks and the Roman empire. It was the basis for much of Eastern Christian history through the continuations that later scholars wrote and for Western Christian history through Jerome's Latin translation of it (late 370s). Eusebius's text implies that all Christian history is divided into six ages, of which the sixth and last age began with Christ's birth. This established a model for dividing up history that most other medieval writers would subsequently use. Sextus Julius Africanus also wrote a text piecing together Roman with Christian history in the late third century that was influential in Eastern Christendom.

As the Roman empire changed gradually into a series of smaller kingdoms, Augustine of Hippo (354–430) formally distinguished the role of earthly power from that of God in the City of God. He argued that only the historical events with direct bearing on the state of Christianity mattered for Christian history. He also believed that no government could represent God on earth. Although his works were influential and widely read, this particular aspect of them had almost no effect on subsequent history. Orosius, a friend of Augustine, suggested that the Roman empire's acceptance of Christianity made the empire a holy one.

The new German kingdoms thought of themselves, like the Byzantine empire, as the inheritors of the Roman empire. The *History of the Goths*, which Cassiodorus wrote for King Theodoric, explains how the Goths were descended Romans and thus the next step in the unfolding of the universal history. Isidore of Seville (d. 636) went still further, explaining that the Goths were descended from Japhet, one of Noah's sons. Isidore was not interested in promoting the Roman empire so much as tying the new kingdoms to Christian history in particular, believing each of them to be the stewards of God on earth, contrary to Augustine's teachings. Gregory of Tours (d. ca. 593) gave the same attention to the Franks, while Bede wrote the Christian history of the English in 731.

One of the major problems that Christian historians wrestled with was the age of the world. Their calculations, which were based on historical events, ranged from Bede's calculation that the world was 3,952 years old at the time of Jesus's birth to Sextus Julius Africanus's calculation of 5,500 years. The use of “AD” to calculate years after Jesus's birth came into use around the eighth century; Bede used it in his work.

ERA 5 Intensified Hemispheric Interactions, 1000–1500

This half-millennium-long era begins with Viking settlements in North America, but they were short-lived and had no significant impact on the cultures of any of the peoples touched by the brief encounter. The era ends with the completion of Christopher Columbus's first three transatlantic voyages to the Caribbean and the beginning of the Spanish empire in the Americas, the voyage of Vasco da Gama to India and the origins of the Portuguese overseas empire, the expedition to North America by John Cabot, and the discovery of Brazil by Pedro Alvarez Cabral. The Eastern Hemisphere and the Western Hemisphere were now connected and would never again lose contact with one another. The inevitable result was a global exchange of peoples, cultures, and commodities on an unprecedented scale that profoundly changed the world. The era of increasingly linked and interdependent societies around the globe to ensue was made possible by the accelerating pace of interactions that took place within Afro-Eurasia between 1000 and 1500 CE and, arguably, was also made easier by both the relative isolation of the Americas from the rest of the world during these 500 years and the establishment of significantly large empires in Mesoamerica and South America. Isolation was a significant factor in leaving Native Americans susceptible to Afro-Eurasian microparasites—viruses, bacteria, and other pathogens—that resulted in a sixteenth-century demographic catastrophe of monumental proportions. Almost as significant, the existence of major empires in Mexico and South America, namely the Aztec and Inca, probably made the conquest and colonial exploitation of these areas that much easier by virtue of the regional consolidation that they had achieved. These conquests and their results are central to the period 1450–1770, but the events and factors in both hemispheres that prepared the way for the post-1500 global world are the story of the period from 1000 to 1500 CE.

Intensified Afro-Eurasian Interactions—Africa

Except for the North African coastal areas, Nubia (present-day Sudan), and Ethiopia, Africa lay largely outside the sphere of direct interchange with the various cultures of the Eurasian landmass during antiquity and for most of the so-called early Middle Ages (500–1000). This began to change significantly during this half millennium to the point that it is necessary for us to think of the Eastern Hemisphere as having become an *Afro-Eurasian ecumene*. That is, it was an interconnected community

of peoples who, no matter how far removed from one another by space or culture, had at least some relationship due to the long- and short-distance exchange of commodities, ideas, and even people that tied this hemisphere together. Sub-Saharan Africa's entry into this hemisphere-wide community was due to two major driving forces: trade and religion.

Kingdoms and Empires of the Western Savanna

Trade was the primary factor in the evolution of the great empires of the western savanna, or grasslands, that lay south of the Sahara. The trade between the region of West Africa that came to be known to early Muslim writers as Bilad al-Sudan (Land of the Blacks) and the north long predated the year 1000, having been particularly spurred by the introduction of the dromedary, or Arabian camel, around 300 CE, which made possible the caravans that crossed the Sahara's desolation. By about 1000 CE, four major trans-Saharan trade routes provided avenues for trade in salt, horses, textiles, and other manufactured goods from the north for such items as ivory, hides, slaves, and gold. But long before then, by at least the seventh century, a kingdom known as Ghana had emerged in what is today northern Senegal and southern Mauritania. Centered on its capital of Kumbi Saleh, it controlled and profited from much of this commerce, especially the gold trade. Ghana declined during the late eleventh century and following, in part due to the opening of new gold fields farther east, and during the thirteenth century hegemony over trade passed to a much larger entity, a veritable trade empire, known as Mali, that extended from the Atlantic coast to such major cities along the eastern Niger as Gao and Timbuktu (both in the present-day nation of Mali). At its peak in the early fourteenth century, Mali was one of the richest empires on the face of the earth. Its wealth, largely based on its monopoly over the gold trade, became legendary throughout the Muslim and Western Christian worlds. As Mali weakened militarily in the fifteenth century, primacy passed to the even larger trading empire of Songhai, which was centered on Gao and flourished into the late sixteenth century.

The gold and other products (including slaves) traded within these three polities were powerful magnets for Muslim merchants, diplomats, and even invading armies from North Africa and beyond. The fabled riches of sub-Saharan West Africa were also a spur to Western Europeans. Various Genoese, Catalan, Castilian, and Portuguese sailors set out into the Atlantic during the fourteenth and fifteenth centuries in search of the West African "River of Gold." The result was the discovery and exploitation of the Canary Islands, Madeira, and the Azores; the fifteenth-century presence of Portu-

The fabled riches of sub-Saharan West Africa were also a spur to Western Europeans. Various Genoese, Catalan, Castilian, and Portuguese sailors set out into the Atlantic during the fourteenth and fifteenth centuries in search of the West African "River of Gold."

guese merchants and missionaries along the Guinea, or West African, coast (including their establishment of the first permanent European trading post in continental West Africa in 1482); the eventual rounding of the Cape of Good Hope in 1485; and the Portuguese presence in the Indian Ocean from 1497 onward.

Religion often follows trade, and the Portuguese certainly were avid proselytizers. Before the end of the fifteenth century, the royal family of Kongo, which lay along the lower Congo River, had converted to Christianity and made the faith of the Roman Church the kingdom's official religion. But these Western Christian inroads paled when compared with the spread of Islam in sub-Saharan West Africa. By the mid-eleventh century, Muslims were such an accepted part of the fabric of the kingdom of Ghana that the capital city, Kumbi Saleh, was divided into two entities, one of which was reserved for Muslims, and in 1076 the king of Ghana converted to Islam. Islam became an even greater presence in Mali and Songhai, to the point that it is quite correct to think of them as integral parts of an Afro-Eurasian *Dar al-Islam* (the House of Islam). As was true of Islam elsewhere and of every other world religion, the practices of West African Muslims were a syncretic mix of universal Muslim traditions and traditional ways of life. Thus, the Moroccan traveler and Islamic jurist Ibn Battuta, who visited the sultan of Mali in the mid-fourteenth century, noted approvingly that the people of the western Sudan were avid participants in the Friday congregational prayers at the mosque, but he disapproved of the freedoms enjoyed by their women.

The Swahili Coast

Trade and religion also transformed the face of that portion of the East African coast stretching from Mogadishu (in present-day Somalia) to Sofala (in present-day Mozambique) and brought its inhabitants into closer contact with two great multicultural entities: the family of Islam and the world of the Indian Ocean. This area is known variously as the Land of the Zanj (Persian for "black") and as the Swahili Region (a term deriving from the Arabic *al-sabel*, meaning "the coast"), and its culture, including its vernacular language, is essentially Bantu with strong Arab and even Persian influences. Unlike the trade empires of West Africa, the Swahili world was divided into a number of independent coastal and island cities that were united only by culture. More than anything else, Swahili cities, such as Kilwa and Sofala, were important centers of exchange, serving both maritime merchants from as far away as China and as close as Arabia, whose ships were driven by monsoon winds and currents, and various African peoples of the interior, such as the Shona-speaking builders of Great Zimbabwe, a great stone city in south-central Africa that flourished between about 1250 and around 1350, possibly due to its presumed control of the East African gold trade. Indian Ocean trade items dating from the fifteenth century, including Chinese pottery, have been found as far inland as 500 miles (805 kilometers) from the coast. In addition to gold, important Swahili exports included slaves,

Brought by Arab and Persian merchants, a few of whom took up residence and married local women, Islam began making inroads along the East African coast well before 1000 CE, and with Islamization came urbanization even before the end of the first millennium.

timber, hides, and ivory, with African elephant ivory being far more highly prized than Indian ivory, even in India. The wealth of the Swahili cities so impressed the Portuguese that they attempted to conquer the entire coast in the early sixteenth century, a venture that had limited success and did not end Swahili involvement in the Indian Ocean economy.

Likewise, the Portuguese could not root out Islam in this same region, even though they carried with them a crusading ethos to fight the religion of the “Moors” wherever they found it. Brought by Arab and Persian merchants, a few of whom took up residence and married local women, Islam began making inroads along the East African coast well before 1000 CE, and with Islamization came urbanization even before the end of the first millennium. Nevertheless, it was only in the eleventh century and following that Islam became a distinguishing characteristic of the region and clearly tied its people to the House of Islam that, by 1500, stretched from the Atlantic to the southern Philippines. Like West African Muslims, the Swahili people shared a sacred book and language—the Quran and Arabic—and the Five Pillars of Islam, as well as many other practices, with an Afro-Eurasian-wide community of believers, but their brand of Islam also incorporated a number of indigenous elements. Unlike West Africa, Islam at this time remained confined to the coast and served as a clear marker between the people of the interior and the Swahili.

Jihads and Crusades

Religion could divide as well as unite, but even when it divided parties into fiercely antagonistic entities, it often served as a force for intensifying hemispheric interaction. Such was the case of holy jihads that brought Muslim forces into the heartland of India and into Anatolia (present-day Asian Turkey) and other lands of the so-called Middle East. Such also was the case of the crusades and the jihads they engendered.

Turkish Ghazis

The driving forces behind Islam’s new jihads were recent converts to Islam, Turkish warriors out of Central Asia who began to convert to Sunni Islam in the ninth and tenth centuries largely as a result of their forced recruitment into Abbasid armies as slave-soldiers (*mamluks* or *ghilman*). In the eleventh century, several branches of these new Muslims became *ghazis*, or border warriors. In theory, the ghazi protected Dar al-Islam, the area governed by Sharia, or holy law, from *Dar al-Harb* (the House of War), which was any region governed by infidels (unbelievers), namely non-Muslims. Defense, however, could be and of-

ten was active, rather than passive, in that it involved raiding infidel territory and capturing booty and slaves. Ironically, many of these Turkish ghazis were the progeny of slaves captured in earlier ghazi forays into non-Muslim lands.

Turkish Muslim raids out of Afghanistan and into northern India began in 997 and by 1027 had resulted in the conquest of Punjab, but there was no further advance for the next century and a half. Beginning in 1175, a new series of Turkish invaders, again out of Afghanistan, conquered most of northern India and established the sultanate of Delhi, which lasted from 1206 to 1526. Over these three centuries, tens of millions of northern Indians converted to the Muslim faith. Some converted out of opportunism or due to pressure; many, however, embraced Islam in response to the influence of Sufi mystics, whose wandering *pirs* (preachers) became an integral part of northern Indian life, especially in Bengal. India, already tied to Central Asia and the entire Indian Ocean world by trade as well as by its much earlier exportation of Buddhist and Hindu religious traditions, was now connected to the hemisphere-wide House of Islam. When Mongol invaders devastated Iran and Iraq in the thirteenth century, many Muslim scholars and artists took refuge in the sultanate of Delhi, where they functioned as religious judges (*qadis*) and in a variety of other professions, thereby firmly linking Islamic India to the intellectual, literary, and artistic traditions of the Persian world. Among the many elements introduced by these immigrants were Persian epic poetry, Persian history writing, and the jurisprudence of the Hanafi School of Iraq.

Anatolia, the heartland of the Byzantine empire (330–1453), experienced a similar Turkish-Muslim invasion in the eleventh century and the beginning of a slow process whereby this Asian peninsula was transformed from a bastion of Eastern Christian Orthodoxy into a land that today is known as Turkey. In this case, it was a clan of Turkish warriors known as the Seljuks.

The Seljuk rise to power began with a victory in 1040 over a rival Central Asian Muslim prince and the subsequent conquest of most of Iran and Iraq. By 1055 the Seljuk leader Tughril Beg had expanded his power all the way to Baghdad, where the Abbasid caliph, the “Shadow of God on Earth” and nominal leader of Sunni Islam, named him sultan (ruler), thereby acknowledging that it was Tughril who wielded true military and political power. Other titles bestowed on him were “King of East and West” and “Pillar of Islam.”

In 1071 Seljuk forces routed a Byzantine army at Manzikert in Armenian eastern Anatolia and swept through most of the now largely defenseless peninsula. By 1086 they had also captured most of Syria and were now the dominant Muslim power in western and Central Asia.

The Crusades

Most of the people subject to Seljuk authority in Anatolia and Syria were Christians of various Eastern varieties. Moreover, the Byzantine empire, which was centered in Constantinople, although battered, was fighting

back for control of its lands. It was in that context that in early 1095 Emperor Alexius I appealed to the West for aid in the form of mercenary soldiers. The response was not what he expected. Pope Urban II, head of the Latin Christian Church, launched what later became known as the First Crusade (1096–1099) in order to aid fellow Christians in the East and to liberate Jerusalem, which had been in Muslim hands since 638. The First Crusade armies helped blunt and push back significantly the Seljuk advance through Anatolia and Syria and also captured Jerusalem, which Western crusaders held until 1187 and then, on and off, from 1229 to 1244.

In the course of the crusade and its immediate aftermath, the crusaders established four crusader states in lands that today encompass portions of Turkey, Syria, Jordan, Lebanon, Israel, and the Palestinian Authority. The longest lasting of these four states was held until 1291, the shortest-lasting was reclaimed by Muslim forces in 1150. Whether lasting a half century or two centuries, these states, especially those with Mediterranean ports, allowed for a dramatic upswing in the interchange between the European West and the eastern Mediterranean. Additionally, during the twelfth and thirteenth centuries certain Western crusaders and several European maritime powers gained control of a number of Byzantine islands and lands, including Cyprus, Crete, Rhodes, major portions of mainland Greece, and even the city of Constantinople and adjoining lands. The Byzantines reclaimed Constantinople in 1261, but some of the islands remained in Western hands until the late seventeenth century, whereas other portions of Frankish Greece, as this complex of Western-held islands and mainland is generally known, fell to the Ottoman Turks in the fifteenth and sixteenth centuries.

These Western European colonies in the eastern Mediterranean allowed for a level of maritime transit of goods and people that probably exceeded that of the Roman empire at its height, and with that commerce came cultural exchange. Probably the single most important item

Probably the single most important item gained in these exchanges, so far as Western Europe was concerned, was a taste for and easy access to sugar.

gained in these exchanges, so far as Western Europe was concerned, was a taste for and easy access to sugar. It was on Cyprus, which Western Europeans held from 1191 to 1571, that Italian merchants learned to produce sugar on plantations run with slave labor, a process that other Europeans eventually carried to certain Atlantic

islands in the fifteenth century and to the Americas in the sixteenth century, with consequences of world historical magnitude.

Contrary to popular belief, these eastern Mediterranean outposts were not significant sources for Western Europe's twelfth- and thirteenth-century recovery of ancient Greek philosophy and science as preserved and interpreted by centuries of Arab Muslim scholarship. Spain and Sicily served that purpose. Muslims held parts of Spain (and until the early thirteenth century most of it) from 711 to 1492. Sicily had fallen piecemeal to Muslims between 827 and 965, only to be regained by Norman Frenchmen in a series of campaigns stretching from 1061 to 1091. Re-

ardless of the Christian Reconquista in Spain, which began to get under way in earnest around 1064, and the Norman conquest of Sicily, both lands had strong Muslim presences throughout the entire period of 1000–1500, and what was more significant, both experienced a significant amount of Muslim-Christian interchange.

Travelers to Spain, Sicily, and the crusader states of the eastern Mediterranean were often surprised to discover a high level of peaceful Muslim-Latin Christian interaction, but Spain and the lands of Syria-Palestine were also bloody battlegrounds where holy war—crusade and jihad—often produced massacres and other atrocities by both sides. In the end the Muslims won the war in the east, capturing in 1291 Acre, the last crusader stronghold on the Southwest Asian continent, and Latin Christians won in the west, capturing in 1492 Granada, the last Muslim stronghold in Spain. Even with these victories and defeats, the holy wars went on in the Mediterranean, along the coast of North Africa, and in southeastern Europe well beyond 1500. Arguably, the last great battle between crusaders and jihadists was the siege of Vienna in 1683.

Crusade and jihad were certainly driving forces in both Latin Christian and Muslim societies well beyond the thirteenth century. The Ottoman empire, which grew to massive proportions from around 1300 to 1672, was certainly fueled, at least in part, by jihadist ideology. And crusade ideology became an integral part of the cultural mind-set of Western Europeans. Indeed, the crusade became an endless war against evil, particularly but not exclusively the perceived evil of Islam, with constantly expanding frontiers and theaters of operation. By the mid-twelfth century crusades of conquest and conversion were waged against pagans (and eventually even Christians) in the Baltic, and these crusades dragged on into the early sixteenth century. The search for crusade allies resulted in Christian diplomats and missionaries traveling to Mongolia and China in the period circa 1250 to circa 1350 in an attempt to convert the Mongols and enlist their help against Islam. Certainly the desire to liberate Jerusalem by finding lost Christian peoples, outflanking Islam, and reestablishing contact with the Mongol Great Khan was one of the several motives that propelled the Portuguese and Spanish transoceanic voyages of the fifteenth century.

Conversions to Islam

Despite jihads waged by Turkish ghazis in India, southwestern Asia, and southeastern Europe, Islam during these five centuries spread largely through peaceful means to peoples near and far. This was the case in the islands and along the Malaysian coast of Southeast Asia, where Sufi mystics and merchants were major vectors of the faith after 1200 CE. They were aided in this endeavor by virtue of the fact that the Malay language was already the common tongue of commerce and discourse among the various peoples of the region. As was the case in sub-Saharan Africa, the new faith was married to local customs. Thus, very much like West African female Muslims, Southeast Asian Muslim women were rarely secluded and enjoyed a wide latitude of freedom. As was the case

in East Africa, Islam was largely confined to coastal cities and nearby regions; the people of the interior continued to follow traditional religions.

Two Centers—The Indian Ocean and the Mongol Empire

During these five centuries, Afro-Eurasia had two centers, the Indian Ocean and the Mongol empire, and both were powerful magnets for merchants, missionaries, diplomats, and every sort of other traveler. One was nothing less than a system of winds, currents, and ports that linked peoples from East Africa to South China. The other was the largest land empire in history, stretching from the plains of eastern Europe to the Sea of Japan, from the northern borderlands of Southeast Asia to the edges of Siberia.

The Indian Ocean Ecumene

The Indian Ocean had attracted commerce and travel on a grand scale well before 1000, and through the centuries India consistently served as its fulcrum and chief meeting place. By the early fifteenth century, however, the coastal regions of Southeast Asia were fast becoming almost as important, in part because of the Strait of Malacca through which trade from the Far East passed. A graphic example of this reality is the *Kangnido*, a Korean world map of 1402 (which shows the Mediterranean and also the true shapes of Africa and the Arabian Peninsula). It places an oversized and conjoined India-Southeast Asia squarely in the middle of the map.

Carriers of Indian Ocean trade included Jewish merchants from Cairo; Arab, Persian, Indian, East African, Malay, and Chinese sailors; and even occasional Europeans, to identify but a few of the many peoples who plied these waters. Navies also traveled the sea-lanes. Early in the eleventh century, ships from the South Indian Chola empire captured the Maldives Islands and defeated the fleet of Sri Vijaya, a maritime power that encompassed Malaysia and the islands of present-day Indonesia, all apparently in support of South Indian merchant-shippers. Between 1405 and 1433 seven great Ming fleets under the command of Zheng He sailed majestically through the Indian Ocean, all the way to East Africa and even the port of Arabian Jeddah on the Red Sea, mainly to assert Chinese hegemony and receive tribute from various coastal rulers. A century earlier, in 1341, Ibn Battuta visited the port city of Calicut in

southwestern India and reported that massive Chinese vessels were regular visitors to the port. Each carried 3 to 12 sails and was capable of holding a complement of 1,000 sailors and marines in addition to their wives and children and, of course, the merchants and their retinues, who traveled in comfort in their private cabins.

A century earlier, in 1341, Ibn Battuta visited the port city of Calicut in southwestern India and reported that massive Chinese vessels were regular visitors to the port.

Other evidence shows that he was not exaggerating. Sailing out of such ports as Hangzhou, Quanzhou, and Nanjing in the largest and most technologically advanced ships of their day, Chinese sailors probably ruled the eastern Indian Ocean from the twelfth century through the early fifteenth century. The *Catalan World Atlas*, drawn on the western Mediterranean island of Majorca in 1375 by a Jewish mapmaker in the employ of the Christian king of Aragon, shows a Chinese vessel off the west coast of India and depicts numerous ports dotting that same coastline. Was it any wonder that Western Europeans wanted to find a sea route to the Indian Ocean?

After about 1435, the imperial Ming court decided to turn its back largely on the Indian Ocean. Such ventures as the fleets of Zheng He were too costly and returned too little, and China had more immediate concerns at home, especially along its northern and northwestern borders. It feared the reappearance of the Mongols. In response, it would eventually construct the Great Wall; sometimes intensified hemispheric interactions were just too much.

Invaders from the Steppe and the Mongol Empire

For millennia, the nomadic, pastoral peoples of Central Asia had been full participants in a complex web of relationships with the societies and states that ringed their world. They traded with them, transported their goods, served as their mercenaries, were enslaved by them, and raided and extorted tribute from them as the opportunity arose. Most dramatically, they periodically produced confederations that attacked and carved out kingdoms and empires at the expense of their so-called civilized neighbors. The various Turkish groups that established states in Southwest and South Asia fit into this broad category. So also was the case with the Khitan (Qidan) and Jurchen (also Ruzhen or Nuzhen) invaders of northern China. The Khitans, a proto-Mongol people, established the Liao dynasty (907–1125), which ruled over most of Manchuria, Mongolia, and a strip of northern China. In 947 the Liao khan proclaimed himself emperor of China, even though he held only its northernmost portions. Between 1114 and 1127 another steppe people, the Jurchens out of Manchuria, swept away both the remnants of the Liao state and the brief hold on northern China enjoyed by the native Chinese Northern Song dynasty (960–1126) and established the Jin dynasty (1125–1234), which ruled northern China from its capital at present-day Beijing.

In 1211 the armies of a new confederation, the Mongols, began a sweep across northern China's plains and captured the Jin capital in 1215, and by 1234 they had totally overrun and absorbed the Jin empire. From there they continued their assault on the rest of China, which was fully conquered in 1279. Earlier, in 1271, the Mongol khan, Khubilai (r. 1260–1294), had proclaimed himself emperor of China and adopted a Chinese name for his dynasty, the Yuan (1271 [or 1279]–1368).

All of this and much more had been set into motion by Khubilai's grandfather, Chinggis (Ghengis) Khan (ca. 1162–1227). In a series of

simultaneous western and eastern campaigns, Chinggis and his successors carved out an empire that by 1260 stretched from Ukraine and Syria in the west to the Pacific Ocean in the east, and it was still growing.

The Mongol Peace and Trans-Eurasian Interchange

The Mongol empire was born in great bloodshed. Reportedly, Chinggis Khan ordered the slaughter of the one million inhabitants of Chengdu in China's Sichuan region, and Baghdad's capture in 1258 was accompanied by an equally horrific massacre. After about 1260, however, the Mongols, while still campaigning on many fronts, began to settle down to rule the four constituent khanates of this vast empire. The result was a modicum of trans-Eurasian interconnectedness known with some exaggeration as the *Pax Mongolica* (Mongol Peace), which extended into the mid-fourteenth century.

It was in this period that significant numbers of Western European missionaries, diplomats, and merchants, of whom Marco Polo was but one, traveled all the way to Yuan China. By the end of the thirteenth century, small resident communities of Italian merchants had been set up in China, and a small Latin Christian mission church run by Franciscan friars was also there. Likewise, Dominican missionaries and Italian merchants labored in Central Asia and India.

The Mongol empire began to break up in the mid-fourteenth century due to many factors, not least of which was the Great Eurasian Pandemic, which Western Europeans later called the Black Death.

The Mongol empire began to break up in the mid-fourteenth century due to many factors, not least of which was the Great Eurasian Pandemic, which Western Europeans later called the Black Death. Germs, as well as goods and ideas, were speeded along the trade routes of Eurasia, including *Yersinia pestis*, the bacterium of bubonic and pneumonic plague. The result was massive mortality rates, reaching probably 50 percent in many areas, stretching from China to England from about 1331 to about 1350, with periodic but less lethal epidemics thereafter.

The Mongol empire probably would have collapsed of its own weight and size, but this pandemic surely helped hasten its passing away. Due to this imperial collapse and a number of other factors that combined to sever the land routes that connected the Far West with the Far East, the Western European outposts in China and India dried up and passed away by 1400. But the Western European memory of its former direct contact with the land of the Great Khan was a spur in the fifteenth century to discovering and establishing water routes to the Indies. The unintended result was Western Europe's discovery and exploitation of the Americas.

American Ecumenes

The Americas before 1500 were divided into many thousands of tribes and clan groups, large and small, who spoke several thousand different

languages that belonged to over 200 language families. Some of these divisions resulted in deep animosities, which early European conquerors were able to exploit to great advantage. Cortés, for example, would not have been able to topple the Mexicas' Aztec empire without tens of thousands of Indian allies. Factionalism and civil war also proved to be valuable allies for Pizarro in his conquest of the Inca empire. But well-established avenues of communication and interchange, as well as the urban settlements that served as hubs for these routes and the several empires that promoted and protected them, also helped speed the conquest of portions of the Americas.

The myth of a sparsely populated Western Hemisphere prior to the coming of European settlers is just that, a myth. Population numbers for the Americas before 1492 vary greatly depending on which historical demographer is doing the calculating, but it has become increasingly clear that large areas of the Americas, such as central Mexico and Amazonia in South America, were densely populated, and dense populations meant radiating circles of contact and exchange. The means, methods, and rate of exchange are still largely unclear, but no one can deny that widespread trade networks existed. By 700 CE, for example, maize, which originally was cultivated in the highlands of central Mexico around 7000 BCE, was being grown from present-day Argentina and Chile to Canada. Irrefutable archaeological evidence points to widespread trade networks in a region encompassed today by the southwestern United States and regions of Mexico, and there is plenty of evidence that items such as copper artifacts, shell ornaments, and pottery were exchanged among various Mound Culture groups from present-day Georgia to Illinois.

Such networks were a proverbial double-edged sword. Before the peoples of the Upper Mississippi Mound Culture ever saw a European, they were devastated by Afro-Eurasian diseases brought by Spaniards and their animals far to their south that traveled along trade routes into the heart of densely populated urbanized societies. The result was their collapse as an identifiable culture, although we should note that some of their larger sites, such as Cahokia near present-day East St. Louis, had been on the decline since the early thirteenth century. Likewise, those same Spaniards, the small army of Hernando DeSoto that crisscrossed lands from present-day Florida to Texas between 1539 and 1542, viewed large concentrations of urban settlements, especially in the Lower Mississippi Valley. Those cities and their inhabitants were gone when the next Europeans visited the region almost a century and a half later. Their dense populations had likewise fallen victim to the diseases brought by Desoto's invasion.

Several large American Indian empires also offered Europeans an opportunity to carve out huge colonies once they had gained political-military control of a structure that had already done much of the work for them. Carved out between 1438 and 1527, the Inca empire, in its day, was the single largest empire on earth, at least so far as landmass was concerned. Control over its capital, Cuzco, and its royal family and various noble factions ensured a successful but not always easy or unresisted conquest and cultural transformation of much of South America. To a lesser degree the same was true in Mesoamerica, where the Triple

Alliance, better known as the Aztec empire, held a position of hegemony. The empire was dominated by the Mexica, with two subordinate vassal allies. Spanish control of Tenochtitlan, the Mexica capital, and alliance with the many enemies of the Mexica, such as the Tlaxcalans, almost guaranteed conquest of the Mexican highlands.

Thus, growing hemispheric connections in both the Americas and the Afro-Eurasian world prepared the way for the First Global Age.

—*Alfred J. Andrea*

Environment and Population

Globally, two environmental phenomena overshadowed all others during these five centuries: the so-called Medieval Warming (ca. 900–ca. 1300) and the Little Ice Age, which began around 1300 but extended and intensified for several centuries beyond 1500. Within Afro-Eurasia the single most significant demographic phenomenon was the Great Pandemic of the mid-fourteenth century, which later generations of Europeans came to know as the Black Death. This pandemic stopped dead in its tracks and reversed dramatically Eurasia and North Africa's overall population increase that had occurred during the first three centuries of this era. Data regarding populations in the Americas are difficult to come by and even more difficult to interpret, but it appears that during this half millennium the populations of most regions of the Americas were on the rise, with the greatest increases occurring in Mesoamerica and South America.

A dramatic symbol of the consequences of these climatic and population swings are the two Greenland settlements: the Eastern Settlement on Greenland's southwest coast and the Western Settlement farther north along the west coast. The North Atlantic's milder winters and longer summers and the growing population of Scandinavia contributed equally to the establishment of Norse colonies in Iceland, Greenland, and North America by the year 1000. The Greenland settlements were located in a harsh environment that was made inhabitable for Europeans, who insisted on keeping dairy herds as a major source of food, only because of the Medieval Warming. When the Little Ice Age of the fourteenth century brought with it colder winters and cooler summers, the colonies became increasingly imperiled. Added to that, the great die-off in Norway due to the Black Death further marginalized these faraway colonists. The result was inevitable. The Western Settlement had already collapsed in 1342. The Eastern Settlement lost all contact with Europe sometime in the fifteenth century and probably totally disappeared by 1500. What the Medieval Warming gave, the Little Ice Age took away.

The term "Medieval Warming" is misleading. Whereas western Europe enjoyed the benefits of longer and more productive growing seasons because of a rise in average temperature of one or two degrees Fahrenheit, especially between about 1100 and circa 1250, the high point

The Greenland settlements were located in a harsh environment that was made inhabitable for Europeans, who insisted on keeping dairy herds as a major source of food, only because of the Medieval Warming.

of Europe's so-called Long Summer, the warming was not universal, and even where temperatures did rise elsewhere, the result was not as beneficial as the term "Medieval Warming" might suggest.

Europe continued to enjoy abundant rainfall during this warming trend, although its level of rain fell slightly. The result was a dramatic increase in the lands put under the plow, a more varied diet, and a steep rise in population from about 1000 to the mid-fourteenth century. The great Eurasian steppe, however, which stretches from Manchuria to the fringes of central Europe, seems to have experienced more extreme cycles of warmer and drier weather followed by colder and wetter weather, leading to a seesaw of unpredictable climatic shifts: drought could be followed by a severe winter. For peoples whose very existence depended on the well-being of their herds, these fluctuations appear to have been one of many factors that drove the formation of large aggressive confederations that sought to conquer and occupy more stable and salubrious lands. There is evidence that Chinggis Khan's rise to power coincided with shrinking pasturage due to drier conditions.

Northern China also seems to have experienced a cycle of recurring droughts, which might help explain the dramatic southward shift of the Chinese population after 1000 CE. Certainly the north was now dependent on large shipments of food from China's new center of agriculture in the south. This probably also helps explain the loss of the north to successive waves of Khitan (Qidan), Jurchen (also Ruzhen or Nuzhen), and Mongol invaders beginning in the tenth century. Even when faced with these difficulties, China's population rose dramatically during the Song era (960–1279) until it confronted two successive demographic disasters: the thirteenth-century Mongol invasion and conquest and the fourteenth-century plague.

South and Southeast Asia apparently experienced severe monsoon fluctuations during the period from about 1000 to about 1350. What impact, if any, these drier periods followed by greater amounts of rainfall had on India is impossible to say with any degree of certitude. Were the Muslim invasions out of present-day Afghanistan connected to this? Maybe, maybe not, but whatever it was that drove the invaders into India, drier conditions might have occasioned droughts and famines that weakened Indian resistance to them. Southeast Asia clearly experienced a cycle of severe droughts and floods that probably made the elaborate water management system of the Khmer empire unmanageable. Because this system of canals and reservoirs was crucial to Khmer agriculture and centralized authority, the empire's decline in the fifteenth century and its abandonment of Angkor Wat during the sixteenth century were conceivably consequences of the Medieval Warming.

Sub-Saharan Africa's semiarid savanna region seems to have had numerous long droughts in the eleventh and thirteenth centuries with an intervening period of cooler unpredictable weather. These fluctuations, however, do not seem to have had any significant impact on the trans-Saharan trade that led to the rise of such empires as Mali and Songhai. The dromedaries that carried this trade were just too tough, and their saddles were perfectly made for bearing their burdens.

In the Americas the story was equally complex. The highly urbanized Chimú culture along the arid northern coast of present-day Peru survived periodic droughts and unpredictable El Niños that threatened flooding from torrential rains during the period from roughly 1100 to about 1300. It managed this thanks to two factors: construction of elaborate canal networks that provided adequate water in times of drought and had overflow weirs to handle excess water and a highly centralized administrative system that enabled it to shift resources from one area to another to meet immediate crises. The result was the emergence of a large Chimú kingdom that dominated the entire desert coast from the early fourteenth century to about 1470, when it was absorbed by the Inca empire. The great city-state of Tiwanaku, however, in the Lake Titicaca region of the Andes, began a precipitous downward slide after 1000 CE, possibly due to drought brought about by prolonged cold, dry conditions. By the early twelfth century the city had collapsed, and its people dispersed. Rainfall did not return to pre-1100 levels in the Andes until the mid-fifteenth century when warmer, wetter weather returned, which might have been a factor in the contemporaneous rapid rise and expansion of the Inca empire. In North America, drought appears to have been a factor in the mid-twelfth-century dispersal of the Pueblo people of Chaco Canyon near present-day Gallup, New Mexico, and the abandonment of various cliff-dwelling sites farther north by the late thirteenth century.

Environment can be an influencing factor, but rarely, if ever, does it determine an inevitable historical course. There are too many variables and choices. Hence, the Chumash culture of California's central coast responded to the climatic changes of the Medieval Warming by intensifying its fishing, and its population increased significantly. This in turn occasioned a number of social challenges, such as increased competition and violence, and some environmental issues, such as sanitation problems, pollution, and disease. But the Chumash also created some social and political systems to meet these challenges. The result was a dense population by 1500.

Population numbers for the various segments of the Americas before 1492 are hotly debated, and the debate is made the more contentious by present-day political and social concerns. It does seem, however, that on balance the populations of the Americas were rising throughout these five centuries, with some areas, such as central Mexico, experiencing extreme population density before the native peoples were devastated by Afro-Eurasian diseases. This is not to say that diseases and epidemics were unknown in the Americas before the arrival of large numbers of people and their animals from the Eastern Hemisphere in the sixteenth century and following. But apparently none of those earlier epidemics had the impact of the Afro-Eurasian diseases, especially the pandemics of smallpox and measles.

When it came to pandemics in Afro-Eurasia, none could match that of the onslaught of bubonic and pneumonic plague of the fourteenth century, which probably killed off 50 percent of the populations of Byzantium, Egypt, Syria-Palestine, and Western Europe between early 1347

and mid-1350 and then returned over the next several centuries in increasingly less virulent forms. The so-called Black Death probably originated in Mongol-dominated Central Asia in the 1330s and spread east and west along trade routes. Its true death toll will never be known, and scholars debate its social, cultural, and political impact. What we can say with some certainty is that it ravaged Eurasia from China to England, including India, and it also raced through the Mediterranean coast of North Africa. In densely populated regions its mortality rate was probably from 40 percent to 60 percent, with one in two people succumbing to it being a reasonable guess as to an average.

One set of population statistics might shed some light on this, thanks to reasonably good census records. Around 1100 CE the population of China was about 100 million, with the highest density in the south. This was largely due to an agricultural revolution that involved an expansion of rice cultivation and the introduction of fast-growing multiple-cropping Champa rice from Southeast Asia. By 1207 the Jin empire of northern China had about 53 million persons and the Southern Song empire had about 65 million, many of them concentrated in huge cities, such as Hangzhou. In 1390 China's total population was

half that, about 60 million. Undoubtedly many of those losses were due to indiscriminate, widespread thirteenth-century massacres by Mongol invaders. But it is equally reasonable to infer that a good portion of that drop in population was due to the Great Pandemic of the fourteenth century. It took Western Europe several centuries to return to its preplague population

It took Western Europe several centuries to return to its preplague population numbers. Possibly it did not reach that level until around 1700, despite the introduction of new foods from the Americas.

numbers. Possibly it did not reach that level until around 1700, despite the introduction of new foods from the Americas. China was less slow to recover, despite periodic famines, natural disasters, and rebellions that killed millions. By 1600 its population stood at around 150 million.

Europe's demographic recovery was possibly slowed by the Little Ice Age that began in the early fourteenth century, grew in intensity after 1500, peaked between 1670 and 1710, and ended around 1850. Its global impact has yet to be studied in any systematic manner, but clearly it cooled the Northern Hemisphere, where the weather became stormier and less predictable and made life harder and more uncertain for a peasantry that now experienced shorter growing seasons. The same was true for those who harvested the seas. Fish, Europe's main source of animal protein, moved farther west, driving fishermen all the way to the dangerous but rich Grand Banks by 1500. If we can extrapolate from Western Europe's experiences, the Great Famine of 1315–1322 was an early manifestation of the fact that many summers would be less fruitful and many winters would be more desperate for those people around the globe whose climates became cooler.

In summary, environment and population numbers have always played significant roles in human history, and this was dramatically illustrated during these five centuries by the Medieval Warming, the Little Ice Age, and the Great Eurasian Pandemic. But we must resist the

seductive models of environmental and demographic determinism. As you will see in the entry on the fall of Tiwanaku, historians do not agree on whether or not environment was a critical factor in its collapse. And even if it was, as the Chumash illustrate, humans have choices. Perhaps wiser choices would have prevented collapse, but we will never know. Likewise, significant increases and decreases in population can and usually do have social, cultural, and political consequences, but those consequences vary greatly from time to time and from place to place in both kind and degree. The only constant, as these five centuries show us time and again, is the adaptability, resilience, and complexity of the human species as it faces challenges and attempts to reshape the world to meet its needs.

■ Introduction: From the Great Warming to the Little Ice Age

Climatic shifts can be gradual and barely discernible to the average person or can be sudden and dramatically apparent. It seems that the cold and resultant famine that settled in Europe, especially northern Europe, in the early fourteenth century was of the latter variety, even though the shift was only a few degrees Fahrenheit.

Europeans had settled and farmed many marginal lands during the period of the so-called Medieval Warming, and its population had grown in proportion to this expansion of exploited land. When the climate took a long-term turn for the worse, the result was dramatic famine and die-off, with the most severe crisis occurring in 1315–1317 on an axis stretching from the British Isles to Poland.

Chroniclers of the period provide dramatic testimony that often borders on the melodramatic but that nonetheless gives us vivid evidence of a society in crisis, even when we make allowance for hyperbole.

Compared to the sensationalism of the majority of contemporary chroniclers, John de Trokelowe, a Benedictine monk of Saint Albans Abbey, was almost matter-of-fact in his reporting of the effects of the famine of 1315 on the lands held by the English Crown, namely most of the British Isles and Gascony in France. Yet even he could not pass up the opportunity to offer a hor-

rifically tasty tidbit or two, as the following excerpt illustrates.

“In the year of our Lord 1315, apart from the other hardships with which England was afflicted, hunger grew in the land. . . . Meat and eggs began to run out, capons and fowl could hardly be found, animals died of pest, swine could not be fed because of the excessive price of fodder. A quarter of wheat or beans or peas sold for twenty shillings [in 1313 a quarter of wheat sold for five shillings]. . . . The land was so oppressed with want that when the king came to St. Albans . . . it was hardly possible to find bread on sale to supply his immediate household. . . .

The dearth began in the month of May and lasted until the feast of the nativity of the Virgin [September 8]. The summer rains were so heavy that grain could not ripen. It could hardly be gathered and used to bake bread . . . unless it was first put in vessels to dry. Around the end of autumn the dearth was mitigated in part, but toward Christmas it became as bad as before. Bread did not have its usual nourishing power and strength because the grain was not nourished by the warmth of summer sunshine. Hence those who ate it, even in large quantities, were hungry again after a little while. There can

be no doubt that the poor wasted away when even the rich were constantly hungry. . . .

Considering and understanding these past miseries and those that were still to come, we can see how the prophecy of Jeremiah is fulfilled in the English people: ‘If I go forth into the fields, behold those slain with the sword, and if I enter into the city behold them that are consumed with famine’ (Jeremiah 14.18). Going ‘forth into the fields’ when we call to mind the ruin of our people in Scotland and Gascony, Wales and Ireland . . . Entering the city we consider ‘them that are consumed with famine’ when we see the poor and needy, crushed with hunger, lying stiff and dead in the wards and streets.

Four pennies worth of coarse bread was not enough to feed a common man for one day. The usual kinds of meat, suitable for eating, were too scarce; horse meat was precious; plump dogs were stolen. And, according to many reports, men and women in many places secretly ate their own children.”

The West African Great Warming

The period of dramatic climatic change known worldwide as the Great Warming was experienced in West Africa as a sudden onset of drier conditions beginning about 1100 CE. Changes in the Atlantic currents, sea levels, temperatures, and wind patterns significantly altered rainfall patterns in the region and ushered in a long dry period that lasted until about 1500. The geographic and environmental patterns of the region of West Africa are among the most diverse in the world. From desert to rainforest, no area was unaffected by the era’s climate shift, which in turn altered the ecology and political economy of the region.

The West African climate had been established by about 2500 BCE, which marked the end of the Atlantic wet period. Broad bands of climate zones stretched from east to west and included the expansive Sahara desert in the north, the marginal sahel on the desert’s southern edge, and savanna grasslands that buffered the tropical forest regions closest to the southern Atlantic coast. More than two millennia of drought and desiccation occurred, ending about 300 BCE and finally giving way to several transitional centuries as rainfall became moderate between 300 and 700 CE and then abundant between 700 and 1100. The centuries of wetter conditions fostered the expansion of long-distance trade between the region’s ecological zones and intensified the reliance on the ancient trans-Saharan commercial networks in building political and economic stability.

A drier climate after about 1100 resulted in the expansion of the Sahara and the gradual shift of environmental zones from north to south, eventually increasing the grasslands at the expense of forest. Early West African states such as Ghana had occupied territory that became too dry to support agriculture, and these declined, providing opportunities for other political entities to expand from their more favorable locations. Between 1100 and 1500, decreased rainfall

➤ A DRIER CLIMATE—THE “FALL” OF GHANA

Evidence for the decline of the eleventh-century Soninke kingdom of Ghana was once based entirely on Arab writings, but recent archaeology and oral traditions provide a more complex picture of the interrelated role of ecology and trade. According to surviving written accounts, the kingdom's commercial and political center was besieged by Almoravids in about 1076, not long after the local ruler converted to Islam. The fall of the kingdom was thus interpreted as the result of external forces alone, a view that is no longer tenable.

Archaeologists have found evidence at Kumbi Saleh for what is thought to have been the capital of Ghana mentioned by the chroniclers. Two possible related sites have been linked, one of which may have been the palace and the other nearby site interpreted as the remains of the Muslim community. The separate Muslim trad-

ing quarter is consistent with later cities and towns that have been excavated and studied. Until about 1100, sheep, cattle, and goats were abundant at the site. After about 1100, drought-resistant goats alone were commonly present, suggesting a gradual adjustment of subsistence strategies in response to changing climatic conditions.

Oral traditions tell of the annual sacrifices to a guardian snake in order to ensure fertility and prosperity. One year the intended sacrificial victim was rescued by her lover, and the snake's revenge resulted in drought and disaster for the local community. Both archaeology and oral tradition thus suggest a story of gradual decline, likely the interconnected result of both the drying up of the region's agricultural basis and the loss of gold resources.

—Candice Goucher

opened up the West African forest to savanna cavalry and allowed warrior states such as Mali to enlarge the territories in which horses could be used effectively.

Changing environmental zones also meant agriculturalists had to seek new lands better suited for their traditional crops. Specialized occupations such as blacksmithing relied on charcoal fuel, and its practitioners were forced to shift operations in search of trees. These dynamic political and economic conditions better integrated regional networks and provided inroads for the expansion of Islam, trade, and technology. After the second half of the fifteenth century, the arrival of European coastal traders ushered in a new era of instability when once again the climate changed sharply to wetter conditions between 1500 and 1630.

The East African Great Warming

The period of the Great Warming from 1000 to 1300 affected the environment and demography of East Africa in significant ways. While many parts of the world experienced a warming in temperatures during this period, with great benefits for agriculture and population growth, the Great Warming in East Africa is most noted for periods of severe drought throughout the region. Data collected by measuring the flood levels of the Nile River in Egypt, which finds its source in East Africa's Lake Victoria, and from analyzing the water levels of other East African lakes suggest that the tenth and thirteenth centuries were times of very little rainfall for the region. Lakes Naivasha, Tanganyika, and Malawi, in addition to Victoria, experienced exceedingly low water levels in the eleventh century.

The peoples of East Africa during this period were comprised primarily of Bantu-speaking agriculturalists, who largely occupied the region by the eleventh century, and a smaller population of Nilotic-speaking pastoralists. The prolonged droughts during the Great Warming made agriculture very difficult and limited the population growth of the Bantus. The largest congregations

THE NILE HYDROMETER

The earliest known Nile Hydrometer, known also as the Rhoda Nilometer, or the Rhoda Column, was constructed in 715 CE by the Umayyad caliph Sulayman Abd al-Malek, although there probably were hydrometers at this site as far back as pharaonic times. Located on a small island in the Nile River close to Cairo, the Nile Hydrometer was built to measure the river's flood levels, a constant and major cause of concern for the rulers of Egypt. Destroyed by an unusually high flood in 850, the hydrometer was reconstructed at the command of the Abbasid caliph al-Mutawakkil in the latter half of the ninth century, possibly under the supervision of the astronomer al-Farqhani, known in the West as Alfraganus. It was subsequently rebuilt in 1092 by the Fatimid caliph al-Mustansir.

The hydrometer is an octagonal column set inside of a stone pit into which the Nile waters flow from three different directions. In addition to verses from the Quran, the hydrometer is marked off with a scale of 19 Egyptian cubits with which to record the Nile's flood levels. Providing scholars with a nearly 1,500-year record of flood levels, including the years of the Great Warming from 1000 to 1500, the Nile Hydrometer is a significant source of climatic information regarding much of East Africa because the Nile begins at Lake Victoria, in the heart of East Africa, and is further watered by runoff from the Ethiopian Highlands.

—Phillip A. Cantrell

lived near the lakes, which, as noted, experienced substantially lowered water levels throughout the era. Thus, while many areas of the world, such as in Europe, the western regions of sub-Saharan Africa, and Great Zimbabwe in southern Africa, saw the rise of more centralized kingdoms in the period from 1000 to 1300, no such centralized kingdoms were established in East Africa. The climate, impacted by drought, served as a severe check on population growth and concentration.

The cattle-herding Nilotes of East Africa existed in small stateless societies and sought out what grasslands they could to herd their livestock. The Bantus generally found agriculture to be a persistent challenge and as a result existed in small scattered chieftaincies across a region

Nineteenth-century Illustration of the Nile Hydrometer on Rhoda Island near Cairo, Egypt. (Library of Congress)

encompassing the present-day nations of Kenya and Tanzania. It was not until after the fourteenth century that one finds significant state growth in the form of centralized kingdom states. The best example of this is the rise of the Buganda Kingdom on the northern shores of Lake Victoria in present-day Uganda.

As a result of the drought-inducing Warm Period, the peoples of East Africa failed to develop political centralization until much later than most areas of the world. By the time of Western contact, East Africa in general and Kenya and Tanzania in particular did not possess sufficient political and state development to resist European coastal incursions and settlements. In very many ways, the region is still in the process of recovering from its delayed political development.

—Phillip A. Cantrell

It Was Not All Wine and Roses—Incidents of Famine in Europe

Films and novels tend to romanticize medieval European life with idealized depictions of King Arthur's virtuous knights or Robin Hood's merry forest rangers. The reality was often more harsh and certainly more complex. Economic status and geographical location played a great role in determining if someone had a relatively comfortable life. Each social class and culture came with a package of social expectations, but common to all was the fact that people generally valued the community over the individual. Such communal traditions and bonds helped to ensure the survival of villages and families. Despite various ways and means, such as pooling farm equipment, that were aimed at building a community that could withstand hard times, unforeseeable natural disasters occasionally shook cultural foundations to the core. One such chronic yet unpredictable force was famine.

A famine is when people run out of food, but historically the term tends to be applied to large-scale food shortages that affect many people. In the most notorious famines many people died of starvation, but more often individuals simply suffered from malnutrition, eating some food but not enough. Malnutrition set the stage for weakened immune systems and the spread of diseases. Some medical conditions, such as pellagra, resulted directly from a lack of vitamins and minerals that humans need to be healthy, whereas other diseases, often of the communicable type, took advantage of ill health and spread among weakened populations.

Fear of hunger held a powerful grip on communities, which knew that harvests could fail at any time locally or regionally, and a massive famine that carried widespread death in its wake was an ever-constant danger. One example was the Great Famine of the early fourteenth century that lasted seven years, from 1315 to 1322, and

Four Horsemen of the Apocalypse symbolizing famine, death, war, and plague. Woodcut by Albrecht Dürer, 1498. (Jupiterimages)

was widespread throughout Northern Europe. Thirty million might have lived in the affected area, and uncounted but probably large numbers of people died as a result of this great hunger.

In the face of such grim realities, some persons turned to religion in order to seek the cause of, possible prevention of, and cure for famine, the dreaded Third Horseman on a Black Horse of the Book of Revelation (Rev. 6:5–6). The truly religious, who trusted in Divine Providence, condemned those who hoarded food as persons who sinned against both God and humanity. Such persons failed to see that God's righteous wrath directed these calamities on a sinful humanity that had to repent its evil ways, and they likewise sinned by failing to show charity to their fellow Christians. But given human frailty, it is likely that more persons chose hoarding over prayer and penance as a preventative and cure

► THE GREAT FAMINE OF 1030–1033 AS REPORTED BY RALPH GLABER

Our best sources for the history of medieval European famines are eyewitness accounts. However, although such testimony can be vivid and detailed, it is not necessarily reliable. People's memories fade, and writers embellish accounts to add excitement and provide plausible explanations. Even so, we still owe much of our knowledge of the Great Famine of 1030–1033 to observations and reports recorded by the French chronicler Ralph Glaber (Ralph the Bald, 985–1047) in his *Five Books of Histories*, which largely traced the history of France from 900 to 1044. Glaber tells of the horrors of the famine, but we have to be careful readers.

Writing from the Benedictine monastery at Cluny in Burgundy, Glaber tried to recount and explain how a famine swept through Western Europe. Like many Latin Christian writers of the period, he saw contemporary immorality as a chief cause for the catastrophe in an upside-down world

where sins had become common and virtues rare. Perhaps as a symbol of this topsy-turvy world, he reports that people were forced to eat unclean beasts. Worse, according to Glaber, others were reported to have resorted to cannibalism, eating even the bodies of family members; he claimed that mothers ate their babies and that grown men devoured their mothers. How real and widespread such cannibalism was is open to question. Glaber seems to have believed that the end of the world was imminent, and he might have been more influenced by apocalyptic visions and wild rumors than by sober evidence and credible testimonies.

Glaber also mistook an accompanying medical condition called St. Anthony's Fire, or ergotism, as a God-directed plague. In reality, it was a fungal poisoning from contaminated rye bread. Chemicals in the rye constricted blood vessels and caused gangrene, convulsions, and death.

—Steven Sams

and thought of their own and their family's survival before that of others.

Given the paucity of our sources and the lack of anything approaching scientific exactitude in those that we do possess, historians find difficulty in tracing the exact causes of any particular medieval famine. Harvests failed for many reasons: pestilence, bad weather, war, or damaging farming practices. Problems in distribution also created crises; if food could not be moved to populations because of a conflict, then those unlucky folks starved. The same issues that affected crop production affected livestock as well, so food animals starved or sickened alongside the families that depended on them.

Governments at the city and regional levels often tried to store surpluses in case of disaster, but authorities could rarely supply these storehouses with enough provisions to last past two major catastrophes or crop shortages. Furthermore, the vast majority of peasants were subsistence farmers: they grew only enough for their families to survive. Another problem was crop specialization whereby farmers grew a particular product in one area and depended on the importation of other necessities from other regions.

In the face of weather and water conditions that could cause schools of fish to wander far from traditional fishing zones, fishing villages offered no absolute security as well, and similar issues applied to coastal towns where seafood provided a major protein supplement to the diet. In an era when the opportunity to move to another more prosperous location was scarce, peasants and townspeople alike had little else but to hope that God and fate would be kind.

Environmental Stresses on the Nomads of the Central Asian Steppes

Central Asia is divided into two major ecological zones. To the north are the steppes, the home of the nomads who were (and are) primarily pastoralists, dependent on the health and welfare of their flocks for survival. The southern zone is the zone of farmers and sedentary peoples. Movement of nomads from their traditional area into the south caused a political, economic, and social disruption. During the period 1000–1500 pastoral nomads, such as the Mongols, shook the foundations of many states and societies on the fringes of the great Eurasian Steppe and became, in some instances, state-builders themselves.

The lifestyle of nomadic groups is romantically envisioned as a carefree existence where all needs are met by nature, with nomads moving freely about the steppes. In reality their life was (and is) far from idyllic. Pastoralists wage a constant battle with their environment in order to survive.

Historically, pastoral nomads were found in marginal regions unsuitable for agriculture. In the Central Asian steppes rainfall was sparse but the soil was rich, producing a thick, heavy turf that was impossible to penetrate with existing plows. Those living in the steppes had to exploit the land indirectly through pastoral nomadism.

Central Asian herds were composed in varying proportions of sheep, goats, horses, and camels (largely Bactrian camels, except for some southwestern regions of the steppe, where Arabian dromedaries were to be found) with the addition of yaks at higher elevations. These herds provided food, shelter, clothing, and trade goods, and the variety of animals in a herd helped improve the odds of the nomads' survival. Equally important were the location and quality of water and grass that, along with tradition and agreements with other herding groups, determined a particular group's migratory patterns. As is true in all areas where resources are limited, clashes over prime grazing and watering areas were common.

Weather was the nomad's greatest enemy. Spring rains plus snowmelt swelled rivers and made crossing them dangerous. Adult animals,

➤ WILLIAM OF RUBRUCK DESCRIBES THE WEATHER

Early European travelers to the steppes of Central Asia commented on the unpredictability and severity of its weather. William of Rubruck, a Franciscan friar, traveled to the court of Mongke Khan in the mid-thirteenth century more than 20 years before the arrival of Marco Polo in China. As part of his extensive writings on his trip, he described the weather of the steppes.

“That morning the tips of my toes froze, with the result that I could no longer go around barefoot. The cold in those regions is most intense, and from the time it begins to freeze at no point does it stop until May. In fact, even in May it froze every morning, though during the day it thawed in the heat of the sun. But in the winter it never thaws, the ice remaining in the absence of any wind. If there were a winter wind there such as we have, nothing could survive, but the air is always calm until April and only then do the winds get up. And at the time we were there, around Easter countless animals were killed by the cold which came on the wind. Only a little snow fell there in the winter but around Easter, which came in the latter half of April, it fell in such quantities that it filled all the streets of Carcorum [sic] and had to be carried away in wagons.”

weakened from a long winter on limited rations, forded the rivers at great peril, and unsheared sheep easily drowned when their coats filled with water. However, waiting for the rivers to subside meant that animals could starve to death in the meantime. During the summer, droughts meant that grass did not grow and animal weight and milk production dropped. During extended droughts large numbers of animals died, but moderate summer droughts were also dangerous. Animals weakened from lack of food and water had a lesser chance of surviving the winter.

In the winter animals could push aside or paw through small amounts of snow to reach

the grasses below, but heavy snows meant death. Horses, the best-adapted animals, were able to paw through thick snow layers of 15–20 inches (40 to 50 centimeters), but deeper snow meant starvation. When a snow became covered with a layer of ice, the danger increased. This condition, called a *dzbut* or *dzud*, could be disastrous. If the ice layer was thick, even horses could not penetrate it. Once the snow was past, the danger was not over. A late frost could kill the early growth of grass and devastate a weakened herd.

Climatic pulsations, or longer-term weather changes, also had an impact on the lives of pastoral nomads, although if the changes developed gradually they were easier to survive. Climatic pulsations provide one theory for the initial southward movement of the Turks and Mongols. A shift to a cooler, drier climate increased snowfall in winter and reduced summer grass growth. The Mongols and other groups were forced to expand their territories to feed their herds. This brought them into contact and conflict with nomadic as well as settled peoples.

It is even possible that the climate shifts and forced movements south could have precipitated the development of Turko-Mongol empires. As these groups found themselves without adequate surrounding land for grazing, they became sedentary and began farming.

Fall of Tiwanaku

The apparent harshness of the Bolivian high plains, or *altiplano*, where the capital of the Tiwanaku state lay along the southeastern shore of Lake Titicaca, has long provoked questions about this state's relationship with the environment. Early-twentieth-century explanations of the monumental complex at Tiwanaku proposed that it

was created at a time when the Andes Mountains had yet to reach their present height and was abandoned when the plateau rose too high to sustain its population. Such fanciful explanations have long been abandoned, but scientific data on the ancient environment of the Lake Titicaca basin have given rise to debates about whether or not climate was a critical factor in the decentralization of the Tiwanaku state and the site's abandonment between the tenth and early twelfth centuries CE.

Support for the environmental collapse of the Tiwanaku system stems largely from the work of Alan Kolata. Begun in the 1980s, Kolata's Wila Jawira Project endeavored to explore the ancient environment of the Titicaca Basin and interaction between agricultural land reclamation projects and paleoclimate (the climate of the past). The project examined data from several sources including ice core data from the Quelcaya glacier, geological cores from Lake Titicaca, and pollen and stable isotope analyses. The Quelcaya glacier, located 120 miles (200 kilometers) northwest of Tiwanaku, reveals wetter/colder periods during 610–650 and 760–1040 and drier/warmer periods during 540–730 and 1250–1310. Glacial cores also revealed heavy dust accumulation in roughly 600 and 920. Other data have been interpreted as consistent with the ice-core data.

The Wila Jawira Project researchers concluded that climate had a major impact on the Tiwanaku state. Tiwanaku developed during a period of relatively high precipitation. This enabled state development and management of raised agricultural fields in the Tiwanaku and Katari river catchments, causing the high dust accumulation in the glacial cores around 600. This development resulted in high agricultural yields and the enhancement of the Lake Titicaca fishery. The wetter climate also allowed Titicaca Basin populations to foster colonies in places like the Moquegua Valley of Peru and the eastern Andean region around Cochabamba, Bolivia, that could supplement the agricultural production of the core region.

Published rainfall charts show that after 800 the Titicaca Basin and surrounding zones became progressively drier and warmer on average. A major downturn occurred about 1040, with se-

vere drought following between 1245 and 1310. Kolata and his research team argue that this environmental shift had a deleterious impact on the agricultural system supporting the Tiwanaku state both in the core region and in more distant colonies. As rainfall decreased the water table dropped, rendering many of the existing raised fields useless and damaging fishing in Lake Titicaca.

In the wake of declining precipitation, environmentalists argue that the people of the Tiwanaku region made socioeconomic changes. They constructed additional fields closer to the retreating lakeshore, contributing to the dust found in the 920 layer of glacial cores. As the lake vanished, people rethought their reliance on its resources. Data from regions such as the Moquegua Valley suggest that former colonists distanced themselves from the highland state apparatus, pursuing their own interests. People destroyed state-associated architecture, looted tombs of the elites, and abandoned the cultural and religious symbols of the Tiwanaku state. In areas to the east of the altiplano, where inhabitants may have been less strongly incorporated into the state to begin with, people reverted to an inward (local) focus, severing highland ties.

Several researchers, however, now question the influence of the environment on the Tiwanaku system. Arguments against environmental explanations take several approaches. First, state control was not needed for the construction or maintenance of the raised field systems, as demonstrated by similar field systems constructed before and after the period of the Tiwanaku state. Second, the climate data do not correspond well with the fortunes of the state; the worst of the drought occurred well after the monumental core was abandoned. Third, a reliance on environmental explanations mischaracterizes human behavior. It overestimates the awareness that people have of their own environmental situation while underestimating their ability to cope with environmental fluctuations. As a result, many now conclude that social stresses associated with converting a confederation of related polities into a centralized state were equally to blame, if not more to blame, for the Tiwanaku downfall.

—Jo Ellen Burkholder

➤ RAINFALL AND PALEOCLIMATIC IMPACTS

What do rainfall averages really tell us about ancient climate and agricultural potential? The answer is that it may have a lot to do with interpretation. One problem is that climatic data from ice cores and lake sediments can mean more than one thing. Thick layers of ice, for example, can imply higher rainfall, colder temperatures, or some combination of both. In the same way, heavy lake sediments might signal erosion or construction of raised fields. To resolve these issues, researchers need additional data from the area in question.

Two other problems involve how well data help us understand ancient farming. First, averages from ice and lake cores cannot tell us at what time of year the rain fell. Precipitation in any quantity at the wrong time of year can seriously disrupt agricultural practices, as can colder or warmer temperatures. Second, rainfall indicators represent aggregate data, not an exact plot of where rain actually fell. Since rainfall can vary considerably from place to place, aggregate data may not tell us how well farmers in any one location actually did during a given time frame. To date, we do not have the ability to dramatically improve these kinds of resolution issues to give us a more complete picture of human-environmental interactions.

Drought in North America, Losers and Adapters—Anasazi, Hohokam, Mimbres, Mogollon, and Chumash

During the early eleventh century (990–1060 CE), the middle twelfth century (1135–1170), and the late thirteenth century (1276–1297) several long-term, large-scale droughts occurred in North America. Climatic data indicate that these

droughts may have affected over 50 percent of the western United States. Furthermore, tree-ring data indicate that the droughts of the mid-twelfth century and the late thirteenth century were of a larger scale and affected a wider region of the contemporary western United States than the drought of the early eleventh century and that the 1276–1297 drought was great enough to have substantially touched even parts of the Plains and Mississippian regions.

The Southwest region was particularly affected by these droughts, and each triggered regional demographic shifts of local peoples. The Anasazi peoples (also called the Ancestral Puebloans) of the Four Corners region, for example, had to move east to the Rio Grande area as a result of the first two droughts. During the first drought many of the great houses in the central Anasazi area were vacated, while archaeological data indicate that the second drought resulted in large-scale population decline of the Four Corners region. These multiyear drought periods were characterized by reductions in both winter and summer precipitation, resulting in a depletion of available resources.

These two major drought episodes also contributed to significant change in the adaptive strategies of the Virgin Branch Anasazi, who occupied the southwestern Great Basin. Archaeological data indicate that the first drought promoted the adoption of several alternative buffering strategies, including new agricultural practices, increased reliance on storage, and the organization of large residential labor groups. The second drought, which followed 150 years of favorable climatic conditions and high levels of population growth, had a devastating impact upon the Virgin Branch Anasazi, resulting in rapid population decline of the entire region.

In present-day southern Arizona, the people archaeologically identified as Hohokam also experienced demographic changes as a result of these droughts but of a less extreme magnitude. Evidence based on a combination of macro-regional population studies and local research in the lower San Pedro River valley of southern Arizona, for example, indicates that only a gradual population decline occurred through the first two droughts, while the third drought resulted in a large-scale demographic change.

In the eastern Mimbres area of southwestern New Mexico, these droughts resulted in a shift in the population demographics rather than regional abandonment or large-scale population decline. Architectural, ceramic, and chronometric data provide evidence for occupational continuity and growth of small residential sites during the late eleventh through twelfth centuries in the eastern Mimbres area in the context of the depopulation of large villages. This regional reorganization in settlement indicates that Mimbres populations mitigated the impacts of the various droughts by relocating to nearby zones with more favorable resources.

These droughts also affected the prehistoric Native Americans living in the Mogollon region of southwestern New Mexico and southeastern Arizona. Similar to the neighboring Mimbres area, archaeological evidence indicates that the first two droughts resulted in minor shifts in resource use and demographic densities, that is, some areas increased in population while other areas decreased. By 1250, however, with the beginning of the late-thirteenth-century drought, many subregions including Pine Lawn, Reserve, Hay Hollow, and Jornada-El Paso rapidly declined in population density. As in the Mimbres region, however, evidence indicates that people simply moved to areas with better natural resources, as several Mogollon areas grew in size during this same period, such as Show Low, Pinedale, Four Mile, Point of Pines, and the Grasshopper regions.

To the west in California, these droughts also appear to have had an influence, although not as significant as in the desert Southwest. In the Chumash region of southern California, for example, around present-day Santa Barbara, the first two droughts appear to have had a significant impact in the development of local sociopolitical complexity. Unlike the peoples of the Southwest, who relied heavily on agriculture, the maritime subsistence way of life of the Chumash contained buffering mechanisms that were more equipped to respond to the droughts. However, some areas apparently were temporarily abandoned by the Chumash during the peak of these drought periods, only to be reoccupied later when environmental conditions again improved.

How Cold Was Cold? The Origins of the Little Ice Age

For its 4.5 billion-year history the earth has experienced rapid climate shifts, from its early beginning as a fiery core to glacial ice ages. These glacial periods then gave way to warming, the most recent occurring over 11,000 years ago, creating the more stable climate we currently enjoy. Within these severe climate shifts have been milder shifts, one of which is known as the Little Ice Age.

A period of unusually warm weather reached its height in 1200, giving way to a steady decline in temperature until the mid-1800s. The period of this cooling has been called the Little Ice Age. Although average temperatures at this time were only 1.8 to 3.6°F (1 to 2°C) lower than present, the drop had a large impact on climatic conditions and thus certain societies.

Many climatologists and historians date the beginning of the Little Ice Age to the fifteenth century, as expanding glaciers increasingly cut Greenland off from sea travel. However, archives, journals, and excavations reveal cooling conditions affecting the Northern Hemisphere by the

➤ JEAN DUC DE BERRY'S BOOK OF HOURS

Depictions of winter in European art were rare before the fourteenth century. Among the first was within *Très Riches Heures du Duc de Berry* (The Very Rich Hours of the Duke of Berry), an illustrated book of prayers commissioned by the duke in 1410. It is highly regarded as one of the most exquisite book of hours in existence and is notable for its portrayal of harsh winter conditions.

A book of hours is an illustrated medieval manuscript of texts, psalms, and prayers serving as a guide for Latin Christian worship. *Très Riches Heures* is 416 pages long, and half of the pages are illustrated. Most of the illustrations are filled with details on the prayer and labor rituals of the seasons and the degrees of the zodiac. For this reason manuscripts such as *Très Riches Heures* not only serve as an archive of religious beliefs and social life but also offer a glimpse into weather patterns.

—Christine Shearer

thirteenth century, as sea ice was already spreading around Greenland and as early frosts and crop failures hit Poland and Russia. In addition to the cooling, much of Europe experienced unusually warm, mostly dry summers (known as the Medieval Warm Period) until the weather turned unpredictable at the turn of the fourteenth century, leading to the Great Famine.

The famine is often traced to a series of large rainstorms that pounded Europe from 1315 to 1322, turning fields into lakes and flooding city streets. Not only did hundreds die from landslides and flooding, but the sustained rain ruined arable land and cut off trade routes, leading to widespread hunger. In search of food, many people migrated from rural areas to cities, and the concentration of people weakened by famine contributed to outbreaks of disease. Populations throughout Europe dwindled.

Oral legends, as recorded much later by European settlers in parts of present-day Canada and the northeastern United States, indicate that the effects of cooler climate were noticed by Native Americans in the early fourteenth century although less severely than in Europe and primarily

in the form of colder, longer winters. Native Americans in western North America also reported tribal famines at this time due to changing weather patterns.

While the period known as the Little Ice Age primarily affected the Northern Hemisphere, particularly the North Atlantic, research indicates cooling effects worldwide, although the timing and nature vary across regions. There is, for example, limited tree-ring evidence for cooler climatic conditions in China starting in the 1300s, while research and archives on ice caps in the Andes show glacial advance starting around 1250. Due in large part to present-day human-influenced global warming, the interest in climatology is growing, as is the research and understanding of its effects on different societies before the Little Ice Age.

Fourteenth-Century Famine in Europe

The cataclysmic Great Famine that afflicted Europe for seven years (1315–1322) radically diminished the population through widespread starvation and malnutrition and preceded the Black Death, which would further decimate Europe. The famine was accompanied by massive climatic changes resulting in floods and animal diseases that killed off masses of livestock, worsening the lot of the starving throughout Europe.

Despite the development of new agricultural tools and methods that contributed to higher harvest yields and a long period of mild weather (the Long Summer, ca. 1000–1300), which allowed European farmers to bring marginal lands into cultivation, Europe prior to the fourteenth century was plagued by periodic regional famines due to bad harvest cycles. The Great Famine, however, exceeded the scale of earlier famines in that it was widespread throughout most of Europe. More than that, it was an early manifestation of a major climatic shift that historians know as the Little Ice Age (1300–1850).

Despite these earlier, more localized famines as well as wars, epidemics, and an endemic high infant mortality rate, from about 1000 to around

► MEMORIES OF THE FAMINE FROM THE CHRONICLE OF JEAN DE VENETTE

French chronicler Jean de Venette (ca. 1307–1370), prior of a Carmelite convent in Paris and later provincial (superior of a religious order) of France from 1341 to 1366, wrote profusely about his experiences and his observations of French society. This first excerpt expresses his view of the Great Famine, which occurred early in his childhood. Later in his life, he commented on France's severe climatic fluctuations, illustrating the relationship in the second excerpt between weather and bad harvests.

“Yet you must know that I, at the age of seven or eight, saw this great and mighty famine begin the year foretold, 1315. It was so severe in France that most of the population died of hunger and want. And this famine lasted two years and more, for it began in 1315 and ceased in 1318. Then, suddenly, by God's providence, crops became as abundant as they had been scarce and the famine ceased.”

“The winter of this year 1363 was very severe and long. A hard frost accompanied by frequent snowfalls persisted almost to the end of March, when it broke at last. In midwinter, it had frozen the vines even to their roots, in several localities, and had destroyed many a nut tree. The sheep and lambs of many districts perished as a result of the cold and the lack of fodder. Bread and other foodstuffs were stored to protect them from the cold in very deep vaults and cellars which had always before kept warm all winter. Yet I saw supplies thus protected brought up frozen.”

—Abraham O. Mendoza

Source

Austin P. Evans, ed. and trans., *The Chronicle of Jean de Venette* (New York: Columbia University Press, 1953), 116.

1300 Europe's overall population increased dramatically, multiplying several times over. Now, however, the Great Famine signaled the beginning of a major fourteenth-century downward spiral in its human numbers. Contemporaries were aware that something of unheard-of catastrophic proportions was taking place, as their testimony bears witness.

Animal murrains (diseases) led to the mass death of livestock, which in turn depleted the already meager diet of Europeans. The scarcity of food led to mass starvation, resulting in an estimated death rate of 10–25 percent in many towns and cities, and those who did not perish were weakened from malnutrition. In turn, this created a greater chance to fall prey to disease. The Black Death emerged soon after the Great Famine and struck down especially those with weak immunity to disease. As famine and disease ran rampant, desperation and starvation led some sufferers into cannibalism: they ate their young or the dead.

The Inuit Move South in Greenland

The present Greenland Inuit people are the descendants of the prehistoric Thule people archaeologically described by the Thule material culture. Beginning 1,000 years ago, these people colonized what is known as the Thule District of northern Greenland, and by the late eleventh or early twelfth century prehistoric Inuit people lived throughout the region. Primarily adapted to hunting sea mammals including large baleen whales, they entered northern Greenland after having spread east across the Canadian Arctic Archipelago during a period of climatic warming.

Greenlanders in polar dress made of animal skins, carrying a spear and a bow and arrow, engraving after a painting made in 1654. (Jupiterimages)

For a century or two their material culture was virtually identical to the earlier Thule culture in eastern Alaska and Canada.

Sometime during the late twelfth and early thirteenth centuries the Inuit people expanded south across Melville Bay to the west coast of Greenland, where archeological evidence indicates that they encountered the Norse. This period has been termed Inugsuk, but the degree of Norse influence on prehistoric Inuit culture as well as the nature and extent of the Inuit-Norse interaction remains uncertain. By the late fifteenth century the Inuit people occupied the entire West Greenland coast as far south as Cape Farewell. Subsequent climatic changes after the fifteenth century, namely the Little Ice Age, have been associated with a decrease in settlement in the northerly regions coupled with migration to more southerly regions. Similarly, during this period evidence indicates that whaling among the Inuit greatly decreased, possibly as a result of

➤ INUIT ORAL TRADITION

Inuit oral traditions from Greenland are clearly divided into two general categories: *oqalugtuat* and *oqalualat* stories. *Oqalugtuat* stories are very old oral traditions that often incorporate supernatural occurrences, mythological creatures, and events from distant times. They are intended to give instructions for proper living, teach social norms, and relate cultural history. *Oqalualat* stories, on the other hand, are accounts of actual events that have taken place within a person's or a community's living memory. These two traditions overlap. Among the recorded *oqalugtuat* (or mythic) oral traditions are several that relate times and events that can be understood as describing the Inuits' southern movement in Greenland. For example, *oqalugtuat* stories discussing the Tuniit reference the people who inhabited the Arctic region prior to the Inuits' arrival. Evidence indicates that the Tuniit were the same people whom archaeologists have labeled Dorset, and oral traditions describe them as a race of large, very strong people whom the Inuit clashed with during their movements. Likewise, the *oqalugtuat* oral traditions of the five brothers describe the brothers' journey across the ice from one landfall to another as they moved down the coast of Greenland.

—Peter N. Jones

increased sea ice. There is adequate archaeological evidence from the decreasing amounts of baleen to argue for a steady decline in bowhead whale hunting after 1400. Rather, evidence indicates that the hunting strategy increasingly focused on seal, walrus, caribou, musk-ox, and other terrestrial animals.

During the late seventeenth or early eighteenth century as the climate began to change again, Inuit social organization and residential patterns also changed. By the seventeenth and eighteenth centuries evidence indicates that the presence of Europeans had a decisive influence on the Inuit communities in Greenland. For example, archaeological data indicate that Inuit communities relocated to European landing places, mostly in the south, for the purpose of trade and exchange.

Changes in Baltic and Atlantic Fishing Patterns

The emergence of the Little Ice Age in the thirteenth century led to unpredictably colder seasons in the Northern Hemisphere that resulted in gradual yet significant changes in the location and patterns of fisheries in the Atlantic Ocean, the North Sea, and the Baltic Sea. Notwithstanding these changes, dried or salted cod and herring remained a European staple. Traditionally the Norse, fishing in the North Atlantic, had used dried cod as sustenance through the long winter months and as rations while at sea. Permission by the Roman Catholic Church in the eighth century to consume fish on Fridays and other days of abstinence increased the demand for dried or salted cod and particularly herring in Europe. Herring, a fish that was widely abundant and easily preserved, allowed the poor, soldiers, and everyday people the ability to consume fish on days of abstinence. At this point, the Basques, Bretons, and English became actively involved in fishing in coastal waters.

The cooling of oceanic waters during the thirteenth century, however, displaced the cod stocks from the European shelf farther into the North Atlantic and forced enormous herring shoals into the North Sea. In the Baltic Sea, more severe winters created a shift in the timing of herring spawning and constricted the fishing season. Although other species such as sprats, flounder, and eelpout were present, the substantially reduced herring catches played havoc on the viability of Baltic fishing. The gradual reduction and displacement of the traditional cod stocks in the North Sea resulted in an overall inconsistent supply of fish, which in turn spurred greater competition among those states and smaller communities depending on fishing as well as certain maritime technological advancements.

THE BUSS

The development of the capacity to catch and preserve herring on ships while still at sea helped the Dutch become a major competitor in the fourteenth-century European fishing industry. This possibility facilitated the engineering of a new sailing vessel, the buss, that accommodated 18 to 30 men over the course of five to eight weeks. Owing much of its basic design to Norse long ships, the buss had up to three masts and a displacement of up to 100 tons. Buss crews used long drift nets to catch herring, which they immediately gutted, salted, and barreled. Outside of the fishing season, this capable vessel was used as a general transport ship. By the mid-sixteenth century, busses in fleets of up to 400 vessels were operating out of Dutch ports.

—Jonathan H. L’Hommedieu

Dutch herring buss, about 1480. (Science Museum/SSPL/The Image Works)

Prior to the fourteenth century, the Basques were in the forefront of maritime technological advancements in Western Europe. English and Dutch advancements in shipbuilding and fishing techniques and the growing political importance of the Hanseatic League, a network of Germanic free cities around the Baltic Sea, resulted in a significant increase in fishing competition and a further decrease in fishing stocks. As large quantities of herring moved into the North Sea, the Dutch invented a much larger ship, the buss. Similarly, the English established mastery of the new Icelandic cod fisheries with the dogger, a maritime vessel that transformed cod fishing. In the 1430s, correlating with the height of political influence of the Hanseatic League, Germanic fishers began competing with the English for the shrinking cod stocks around Iceland. Diplomatic notes were frequently exchanged, fights among fishers were not unusual, and rivals plundered

cargoes. As the cod stock continued to move toward warmer waters in the Atlantic Ocean after the fourteenth century, the English relentlessly expanded their fisheries farther into the Atlantic. As a result of the Little Ice Age, the scarcity of cod and the abundance of herring in the North Sea led the Dutch, utilizing their superior fishing techniques and the buss, to assume the role of one of the most important fishing nations at the end of the sixteenth century.

The Little Ice Age in the Americas

During the Holocene epoch in the Americas (10,250 years before the present), the mean temperature and precipitation levels across both continents fluctuated considerably. This caused regional environments and local ecologies to vary greatly across time, ranging from drier and warmer periods to extended colder and wetter periods. One of these extended cold and wet periods occurred in the Americas approximately 700 years before the present and lasted for close to 400 years. During this period, commonly referred to as the Little Ice Age, annual temperature and precipitation regimes throughout the Americas were several degrees colder and wetter than today.

In the mountains of western North America, for example, evidence indicates that glaciers

reached positions more advanced in the 1700s and 1800s than they had at any time since the last major glaciation at the end of the Pleistocene epoch (approximately 10,250 years before the present). This was primarily the result of a decrease in mean summer temperatures coupled with an overall increase in winter precipitation.

Beginning around 700 years ago and peaking in the early seventeenth century, similar climatic evidence from the Coast Mountains of British Columbia in Canada indicates that the ranges of some plants either retracted or extended, especially near tree lines, in response to changes in mean temperatures of 1.8–3.6°F (1–2°C) as well as to changes in summer snow cover. Likewise, in eastern Canada evidence from the long-term growth performance of black spruce trees indicates that significantly smaller trees grew in the eastern Canadian woodlands during the Little Ice Age than today, primarily as a result of the period's more extreme climate.

In South America, evidence indicates that a similar shift in annual temperature and precipitation regimes took place during the Little Ice Age. For example, sediment core data from southern Chile evidences changes in pollen levels during the Little Ice Age, indicating significant shifts in the intensity of the Southern Westerlies and overall precipitation patterns across the southern portion of the continent. Likewise, ice core data from the Peruvian and Bolivian Andes contain evidence of higher precipitation levels and colder mean annual temperature during the Little Ice Age. Because of the change in the Southern Westerlies during this time, evidence also indicates that some areas east of the Andes experienced drier mean annual precipitation regimes. In the Pampas region of present-day Argentina, for example, sediment data indicate that a cooler, drier environment than today existed for several hundred years during the Little Ice Age.

—Peter N. Jones

► THE EVIDENCE FOR SOUTH AMERICA

The evidence for climate change during the Little Ice Age in South America comes from several types of data. Sediment core records recovered from the bottoms of lakes and wetlands contain records of the silt and pollen and other objects and materials that have fallen over time. The lake water or wetlands act as a preservative, and the silt or pollen deposits fall in chronological order, allowing changes in climate to be documented over time. Sediment cores have been recovered from throughout the continent, but the majority have come from Argentina and Chile. Ice core records are similar, relying on the accumulation of snow and ice over many years that have recrystallized and trapped air bubbles from previous time periods. The composition of these ice cores, especially the presence of hydrogen and oxygen isotopes, provides a picture of the climate at the time. Ice core evidence has been recovered from most Andean countries. The other type of evidence for climate change in South America comes from prehistoric bone assemblages. By examining the types of bones found in particular areas over time, archaeologists are able to deduce the change in environment over time by knowing the ecosystem of that animal species.

■ Introduction: The Human Environmental Imprint—Cities around the World

No one would deny that cities and those who dwell in them have always had a significant impact on the environment, and when they become megalopolises their impact is almost exponentially multiplied.

Between 1000 and 1500 a fair number of massive cities arose around the globe, and smaller cities but of substantial size proliferated on every continent except Australia and Antarctica. The single most urbanized region was China, where cities and towns of every size multiplied and expanded, at least until the Mongol onslaught of the thirteenth century and the bubonic plague pandemic of the fourteenth century, which together resulted in a great deal of destruction, death, and diminution in the numbers and size of the Middle Kingdom's cities and towns. During the early Ming era, however, a rapid recovery was under way, perhaps best symbolized by the creation of a new imperial capital in Beijing, the construction of which was begun in 1406 and initially completed in 1421. Indeed, this was the case for all areas of Afro-Eurasia touched by thirteenth- and fourteenth-century invaders from the Central Asian steppe or by the Great Pandemic: rapid growth in the numbers and size of urban centers for the first several centuries followed by a dramatic reduction of both but then recovery during the fifteenth century and following. Urban recovery in Europe, however, was far slower than in China, although cities such as Florence and Wittenberg provided the setting and impetus for two transformative local movements: the Renaissance and the Protestant Reformation. The cities of the Americas escaped the cruel blows of the thirteenth and fourteenth centuries (their mortal blows came with the sixteenth-century arrival of Europeans), and consequently the Americas'

great and near-great urban areas, such as Tenochtitlan, Cuzco, and Cahokia, could grow in size and complexity in relative security during these five centuries.

Prior to the arrival of the Mongols, many of China's provincial cities could claim megalopolis status. One such great city was Quanzhou, a southern port city in Fujian Province, that in 1120 claimed 500,000 inhabitants within and around the city proper. Due to its large population of resident foreign merchants, the city was a major center of commerce with a world that stretched as far west as northern Africa and Muslim Spain. Another great port city that flourished in the age of Southern Song (1127–1279), when it served as the "temporary" imperial capital, was Hangzhou, which Marco Polo described as the finest and most splendid city in the world. This was high praise, coming as it did from a Venetian whose home city was the center of a great eastern Mediterranean empire. In 1125, roughly a half century before Polo arrived in China, an anonymous Chinese author composed a treatise in praise of Hangzhou titled *A Record of Musings on the Eastern Capital*. In it he lauded its varied and specialized markets, its massive warehouses set along the shores of an artificial lake, and its commercial establishments, especially its teahouses, some of which were notorious for their prostitutes and hustlers. Indeed, what one medieval English writer noted in praise of the qualities of the far-smaller but vibrant London could be equally said of Hangzhou, Quanzhou, and numerous other great cities across the world: The city was a wonderful place in which to live for those who had sufficient money.

What many of these contemporary writers did not remark on—taking it undoubtedly as a given—was the pollution generated by cities and

towns, although some, most notably Tenochtitlan, did a remarkable job of providing fresh water and cleanly disposing of waste. One writer who did comment on urban filth—although it was the filth of the infidel Latin Christian colonists in the Levant—was Ibn Jubayr, an Andalusian Muslim who visited the Latin Kingdom's port city of Acre in 1184. In this meeting place of Muslims and Christians of every variety, he noted that the city stank from its overflow of refuse and excrement.

Yes, cities could be lovely places in which to live for those who could afford them and who were not overly sensitive to noxious aromas. Numerous Chinese silk screen paintings from this period, such as the twelfth-century *Spring Festival along the River* that depicts the Northern Song capital of Kaifeng (960–1126), portray the myriad activities and pleasures of urban life. But pollution and the diseases it bred were equally a morbid and often deadly fact of urban life.

—Alfred J. Andrea

Cities of the Swahili Coast

From southern Somalia to the northern parts of Mozambique, the coast of East Africa is dotted with the ruins of abandoned cities, towns, and cemeteries. Some of these, such as the ruined town of Gedi in Kenya, cover many acres and are littered with the remains of stone-built monumental buildings such as mosques, palaces, and mansions. Others, such as Ras Mkumbuu on the island of Pemba, cover a large area, but most of the remains, except for a few tombs, are visible only to the trained eye of an archaeologist. So common are these ruins that since at least the seventeenth century, ruins have been a favorite theme in the poetic tradition of the coast, allowing poets to contemplate the impermanence of all material things.

The people who built these cities are called the Swahili. The word “Swahili” derives from the Arabic word for “coast”; it is not clear when the people of the coast began to use this term to describe themselves or even when, if ever, they began to think of themselves as a coherent group of people. That the standard name for the people who built the cities and towns of the East African coast derives from Arabic indicates that

although the Swahili are African and speak an essentially Bantu language, they also participated in the larger cosmopolitan world of the Indian Ocean, and these oceanic connections are as much a part of their story as are their local African origins.

The towns that formed the core of the Swahili world at its peak in the period between 1000 and 1500 CE had their roots in smaller fishing and trading towns, some of which date back to the middle of the first millennium. But around 1000 the coast seems to have become more firmly embedded in Indian Ocean trade networks and culture. The result was the Islamization of the coast and the expansion of the coastal villages into towns and cities. Initially these towns were built mostly out of perishable materials (most often mud and wood) with a few public buildings made of stone. Thus, the congregational mosque and the ruler's palace might be made of stone, while the rest of the city would be constructed from sun-dried mud reinforced with termite-resistant mangrove wood.

Like many maritime trading cities, the cities of the Swahili coast were city-states. That is to say, there was no Swahili empire or any other overarching political structure on the coast. Each city was self-governing and controlled its own hinterland, but the political reach of the city leaders rarely extended far beyond the gates of the city. Occasionally one town would conquer another, but immediately the leaders of the conquered city would begin plotting a return to independence, and few defeated cities remained politically subordinated for long. The cities were usually ruled by kings, but the powers of the kings seem to have been rather limited and in many instances symbolic. Some towns would go for long periods of time without a king, suggesting that kingship was not central to government. Rather, the real power lay with elite merchants, who are usually described as *waungwana* in Swahili or as patricians in English. Parts of each city were reserved exclusively for patricians, and it was they who chose one of their number to be king, very much like the Venetian merchant patricians of the same era who elected their *doge*, or leader. Many of these Swahili patricians had the leisure to participate in Islamic scholarship and because of their commercial contacts with

THE CITY OF KILWA

The cities of the Swahili coast went through a major expansion in the fourteenth and fifteenth centuries. The greatest of these was Kilwa, located in what is today Tanzania. Kilwa was perfectly situated to control access to one of the major trade goods of the East African coast, the gold that arrived from the interior at the southern port of Sofala and then was transported up the coast. As Kilwa grew rich on Sofala gold, the size and grandeur of the city grew apace. The traveler Ibn Battuta, one of the best-traveled people of his time, visited Kilwa in 1331 and described it as “one of the mostly beautiful and well-constructed towns in the world.”

When the Portuguese first arrived in Kilwa in 1500, they were astounded. In addition to many stone-built houses, the city contained two huge public buildings. One was the Husuni Kubwa, a vast palace and warehouse complex used by the merchant-princes who ruled the city, and the other was a mosque with elaborate vaulted ceilings that was the largest enclosed space in sub-Saharan Africa. The Portuguese liked Kilwa so much that they came back and conquered it in 1505 and in the process burned down much of the city.

—Erik Gilbert

Arches of the Great Mosque on the island of Kilwa off the coast of Tanzania, fifteenth century. It is believed that the mosque had one of the first domes on the East African coast. (Ikachan/Dreamstime)

Arab merchants often intermarried with visiting or immigrant Arab families. Over time, many of these families began to claim alien origins in either Persia or the Arabian Peninsula, which added greatly to the confusion of scholars in the nineteenth century trying to determine the origins of the Swahili world.

The growing wealth of the patrician merchants resulted in a major transformation of Swahili cities in the middle of the fourteenth century. They began to build their homes of stone rather than mud. The houses they built were large and were meant to demonstrate their creditworthiness to potential business partners. They included guest apartments where visiting merchants could

live and storage areas where their guests could keep their trade goods. Inside the houses were carved plaster niches, called *zidaka*, where imported Chinese porcelain and other signs of wealth could be displayed. Thus, by 1500 the Swahili cities were thriving commercial centers, with both public buildings and elite residences built in stone as well as many commoners' houses built from mud and wood.

Great Zimbabwe—The Built Environment

The massive ruins of Great Zimbabwe (a name derived from the Shona term for stone buildings) in the modern nation of Zimbabwe constitute one of the most important archaeological sites in Africa. Great Zimbabwe consists of three principal ruins: the Hill Ruins, the Great Enclosure, and the Valley Ruins. Together they provide evidence of a thriving medieval African city demonstrating African development, lifestyle, and ingenuity long before European colonizers set foot on the continent.

Human occupation on the Zimbabwe plateau is noted as early as the Stone Age, and a rich record of human activity is found near Great Zimbabwe in the Chamavara and Dengeni caves. The fertile environment provided water, fuel, food, and shelter for inhabitants. By early in the first millennium CE, farming villages occupied a considerable part of the Zimbabwe plateau. It was the centralization of these scattered, small-scale settlements, supported by shifting cultivation and cattle-raising, that gave rise to Great Zimbabwe. Additionally, by the ninth century, gold, ivory, and other products were being traded between the people of Schroda, a village in the Limpopo Valley, and the traders on the seacoast. By the eleventh to twelfth centuries, the rate of development accelerated due to the generational acquisition of wealth and an accumulation of personal property, leading to the creation of stone settlements as a vast display of wealth.

Radiocarbon dating indicates that the first permanent settlement at the Great Zimbabwe site was on the Hill site and consisted of a small village of pole and dacha (clay) huts dating from 1075 ($\pm$ 150 years). Similar radiocarbon dating of the stone walls puts the development of building in stone at Great Zimbabwe at about 1130 ($\pm$ 40 years). Great Zimbabwe's rise to power began in the thirteenth century, and by the start of the fourteenth century the city and state were fully established. It is estimated that at its height, Great Zimbabwe was home to about 18,000 people.

Great Zimbabwe was built in three phases over the course of 300 to 400 years as evidenced by increasing improvement in masonry skills in

the construction of the stone walls. Early walls are sturdy but not neatly built. The stones used in the construction of later walls were carefully matched and fit together so that there was no need to fill gaps between mismatched stones. All stones used to construct the walls of Great Zimbabwe were quarried from the local environment. No mortar was used to join any of the stones.

The designers of the Hill ruins took advantage of the natural beauty of the landscape and utilized the environment to enhance their dwelling places. The Hill ruins are the oldest, and the stone walls are constructed to incorporate massive granite boulders. The Hill ruins show evidence of a number of enclosures. The western enclosure is thought to have been inhabited first and was most likely built to house the royal family. Subsequently, the Great Enclosure was built below the hill, and the royal family relocated to this much grander space. The Hill ruins are thought to have become home to the Spirit Medium, or spiritual leader. The Great Enclosure ruin is Great Zimbabwe's utmost achievement and southern Africa's largest masonry structure. The outer wall of the enclosure is more than 800 feet (255 meters) in circumference and contains some 1 million stones. The ruins of the enclosure were home to five or six separate royal lineage households. The Valley ruins contained approximately 50 separate households living behind the stone enclosures, which demonstrated the power and authority of these families. Residents were most likely the officials of the court and relatives of the king and his tributary chiefs.

Surrounding Great Zimbabwe on nearby hills and granite outcrops, a dozen or more small stone-walled enclosures indicate the existence of dwellings for other members of the elite class. Additional ruins are found between one and two days' walk, and these are thought to be the Zimbabwe, or stone houses, of the junior members of Great Zimbabwe's ruling class or homes and capital seats of tributary rulers. The Great Zimbabwe ruins provide evidence of a thriving culture in the heart of Africa.

Cities of the Western Sudan

Cities of the Western Sudan benefited from the spread of Islam and developed as increasingly significant centers of commercial and religious life in the second millennium CE. Urbanism expanded during the period between 1000 and 1500 as cities in the Western Sudan became sites where artistic and intellectual pursuits flourished. Anchoring the mercantile and political functions of states, the urban centers grew in size and influence.

Urbanism in the Western Sudan had indigenous roots in settlements with strategic access to secure subsistence and trade, independent of state-focused power. Middle Niger River entrepôts such as Jenne Jenou and Gao collected and exchanged the goods and resources from savanna, forest, river, and desert commercial networks as early as 250 BCE. Later centers such as Sijilmasa were founded as departure points for the caravans between the Western Sudan and

North Africa and developed into urban centers by about the ninth century CE. From the Atlantic coast and the Senegal Valley to the vast regions of the Niger, trade in gold, salt, kola, iron, slaves, and foodstuffs attracted people and wealth to cities through the centuries.

As primarily cities of trade, the Western Sudan centers were typically organized into distinct ethnic and occupational quarters based on artisan or trade interests. The arrival of Islam became the catalyst for a more centralized political role. Rulers exacted tribute and taxes from their hinterlands in the form of gold, using the revenues to support armies and protect trade routes. Once rulers and other elites converted to Islam, trade was further enhanced. Mosques were built, and their patronage supported urban arts and learning. Cities became conduits for the transfer of technology, from weaving to metrics. At that time, West Africa may have produced as much as two-thirds of the world's gold. It is little wonder that the centers attracted pilgrims and merchants, whose diversity and wealth in turn promoted a cosmopolitan atmosphere.

While many of the cities of the Western Sudan now are in ruins, the vivid descriptions of Arab travelers remain as testimony to their size and grandeur. According to the fourteenth-century Egyptian scholar al-Umari, the city of Sijilmasa was reportedly a place of imposing architecture, with many high buildings and gated entryways. At the heart of many cities were the palaces and mosques. Cities had broad tree-lined streets, bustling markets, and ports. Religious and ceremonial structures formed the city center and were surrounded by the residences of city dwellers. An eyewitness account by the fourteenth-century traveler Ibn Battuta also described the mud architecture of one city's houses with their timber and reed roofs, suggesting their reliance on local traditional styles. By contrast, mosques and palaces were often designed by foreign architects whose work was supported by the generosity of wealthy patrons. The ruler Mansa Musa (r. 1312–1327) is said to have brought the Andalusian poet and architect Abu Ishaq al-Sahili to the capital city, where he constructed an elegant building, plastered with colorfully painted designs, as well as the Sudano-Sahelian style mosque that dominated the cityscape.

> TIMBUKTU

Sankore mosque and madrasa of Timbuktu, early fourteenth century. (David Kerkhoff)

The city of Timbuktu was founded by Tuaregs as a trading settlement near the end of the first millennium CE and subsequently grew to the status of a major city during the tenure of the Mali and Songhai empires. Situated near the Niger River, Timbuktu developed as a central meeting point for North African salt traders and caravans carrying gold and slaves from the south. There at the interface between environmental zones, goods were transferred from camel to canoe. Because of its location in an area subject to increasing aridity, the community's population was forced to rely on trade for basic subsistence. A center for Islamic learning at its height, Timbuktu was regarded as the key site in the intellectual life of West Africa. More than 25,000 students attended the Sankore madrasa, where they studied theology, literature, and law. Reportedly more profits could be made off the city's book trade than any other commodity.

—Candice Goucher

Toward the middle of the second millennium, the cities of the Western Sudan achieved new levels of refinement. The development of many cities as centers of Islamic learning meant that the urban centers attracted scholars and clerics. Madrasas (schools attached to mosques) were built, including the legendary madrasa of Timbuktu. Most of the scholars were of Sudanese origin, and their presence became a significant force in the intellectual life of West African urban centers, especially at Timbuktu, Gao, and

Kano. But the Islamic influences constituted only one strand in the complex cultural weave of the region. Even in the palace of converted elites, the traditional masquerades could be observed. While very few people could read the Arabic works in city libraries, many sought objects with quranic verses in Arabic script for their protective qualities and ritual uses within African religions. Such syncretism would continue to blend the influence of Islam with the continuities of the African past.

—Candice Goucher

Cities of the Almohad Empire

When al-Mahdi Ibn Tumart (d. 1130) started preaching *tawhid* (the Unity of God, or Allah) in the tiny Berber village of Tinmal in the High Atlas Mountains of Morocco, no one imagined that his reformist movement would give rise to one of the most powerful empires of the Muslim West, the Almohads (from *al-Muwahhidun*, “they who proclaim God’s unity”). Ironically, the art and architecture of the Muslim West owe a great deal of their splendor (e.g., the minarets of the Giralda and Kutubiyya in Seville and Marrakech, respectively) to what started as an austere and puritanical movement. Memory still has it that when the first Almohads entered the city of Fez (around 1145), they hid with a layer of whitewash the stucco decoration found at the Qarawiyyin Mosque because it was deemed too lavish for their taste.

Most of the Almohad architectural achievements were commissioned under the patronage of their first four caliphs. These include congre-

➤ ALMOHAD MECHANICAL INNOVATIONS

If the Almohads went to great lengths to fight innovation in religion (*bida* in Arabic), they showed almost the same zeal in acquiring the latest innovations in science and engineering. The mechanical *maqsura* (royal enclosure) in the Kutubiyya Mosque of Marrakech and the mechanical box for storing a copy of the Quran are two good examples in this respect.

Archaeological excavations around the *mihrab* area of the first Kutubiyya, the wall niche that indicated the direction of Mecca, revealed a set of constructions beneath the floor level that intrigued French colonial-period archaeologists. Their function and their relation to the *mihrab* area above remained a mystery until a historian visited the site and recognized in them the remains of the mechanical *maqsura* described in *al-Hulal al-Mushiyya* (*Embroidered Robes*), a medieval anonymous chronicle of the Almoravids and the Almohads. The *maqsura* was commissioned by Abd Al-Mumin (d. 1163) and designed by a Muslim engineer from Malaga in al-Andalus. It consists of six wooden panels linked to an underground mechanism and covered with mats. When the caliph arrived for the Friday prayer, the mats were removed and the mechanism activated. The panels would then rise above the floor to form a royal wooden enclosure. Once the communal prayer was concluded, the *maqsura* would disappear

Moorish wall design in the Alhambra, Granada. (Alfred J. Andrea)

again, and the space within the mosque regained its egalitarian character as was befitting of Almohad orthodoxy.

It was the same Abd Al-Mumin who commissioned a mechanical box for storing the *Mushaf* (Quran) of the Great Mosque of Cordoba. This Quran was placed on a lectern and stored in a wooden box. The Quran came out of its storage box automatically—via a mechanism (*hila*, Arabic for “ruse”)—as soon as a key was introduced and the box unlocked.

—Said Ennahid

gational mosques, palaces complete with royal gardens, waterworks, and monumental gates and towers. The two structuring principles of Almohad art and architecture are monumentality in scope of projects and simplicity in decoration. Almohad architecture relied a great deal on the construction technique of *tabiyya* (cob work), especially for city ramparts (e.g., Marrakech, Rabat, Fez, and Seville). This technique, as described in the *Muqaddimah* of Ibn Khaldun (written in 1377), consists of a mixture of lime, mud, and gravel poured and rammed into a wooden frame and left to dry. The holes left at regular intervals on North African fortifications—which have often intrigued foreign visitors—were left by the beams that kept the wooden frame parallel and were usually uncovered once the plastering fell off.

The cities of Marrakech (Marrakush), Seville (Madinat Ishbiliya), Rabat (Ribat al-Fath), and—to a lesser extent—Fez (Madinat Fas) are still living witnesses to the Almohad ambitious artistic and architectural program in the Maghrib (western North Africa) and al-Andalus (Islamic southern Spain). The Almohad conquest of Marrakech in 1146 and of Seville in the following year marks the proclamation of the Almohads as the new masters of the Muslim West. The cities served as dynastic capitals for the Maghrib and al-Andalus, respectively.

Using a religious discourse centered on moral reform, the Almohads obliterated almost all trace of their predecessors (the Almoravids) in Marrakech, including mosques. All that survived the Almohad zeal was an ablution facility (the Almoravid Dome) and a wooden minbar (the pulpit

used for Friday sermons), which was later relocated to the newly built mosque of Kutubiyya. The Almohads expanded the city toward the south by adding a whole new administrative and palatial complex complete with royal gardens (Agdals). Under Abd Al-Munin, Marrakech saw its underground water-draining system perfected. The water was drained from aquiferous strata of the nearby Atlas Mountains, channeled along underground canals (known as *khattara* or *qanat*), and stored in large basins for drinking and irrigation. The experience would be replicated, with minor adjustments, in Seville.

The Almohads entered Seville in 1147 at the request of its dignitaries and left a lasting mark on the city's urban history. Construction of the city's congregational mosque—where the city's cathedral stands today—started in 1172, and work on its minaret, the Giralda, started in 1184. The Almohads made several additions, modifications, and reinforcements to the city's fortifications, especially the segments damaged by the frequent flooding of Guadalquivir River. Water for the Almohad royal gardens in Seville (e.g., the Buhayra place) was channeled using a Roman aqueduct discovered and put to use again by one of the dynasty's hydraulic engineers. It is important to note in this regard that the Almohad dynastic capitals of Marrakech and Seville were also important intellectual and scientific centers that attracted leading scholars of the world at the time, such as Ibn Rushd (Averroes) and Ibn Maymun (Maimonides).

Rabat was a completely Almohad creation. Its urban history began as a modest military camp for dynastic troops heading for holy war against the Christians of Spain. The victory at Alarcos (al-Arak) in Spain in 1195 marked a turning point in the history of Rabat. Yakub al-Mansur, using the spoils of Alarcos, wanted to build a city, Ribat al-Fath, worthy of Almohad aspirations to create a real empire of the Muslim West. The city's congregational mosque, Hassan, was second only to the Great Mosque of Samarra in Iraq, the largest mosque at that time throughout the Muslim world. The fortifications and the two monumental gates of Bab Ruwah and Bab Udaya date to this period. However, Yakub al-Mansur's great expectations for his capital never materialized. Soon after his death in 1199, his building sites

were abandoned, as evidenced by the half-finished Hassan Tower still standing today.

The Alhambra and Avignon

The Alhambra in Granada, Spain, and the Palace of the Popes in Avignon, France, have similarities expressed both physically and symbolically. Although not separated by great distances, an Islamic palace-city built by the Nasrid dynasty (1232–1492) and a second residence constructed for the papacy are traditionally considered worlds apart, falling on opposite sides of a dividing line between East and West that dismisses any possible resemblance. Nevertheless, the permanent home of the last Islamic rulers of Al-Andalus and the residence of the Latin Christian, or Roman, popes before and during the Great Schism (1378–1415) served as fourteenth-century royal residences within both sacred and secular contexts.

The Alhambra and the Palace of the Popes were both fortified locations, near a river and an adjacent town. Within the walls were living quarters with ornamental and agricultural gardens, reception halls, markets, and religious spaces for public and private observance. There were a prison, a mint, a cemetery, barracks for troops, and housing for service workers. Most of these secondary institutions were located in a specific area of the palace-city and did not use more than one-third of the available space within the walls, for these services were not a priority. Both locations were designed for permanent habitation and included a specialized population for the daily functions of the palace-city and to serve its greatest purpose: attending to the most important inhabitant, whether pope or sultan. Because of the surrounding walls, both experienced space limitations that required

Casbah (fortress) gate in Almohad Rabat, Morocco.
(Alfred J. Andrea)

destruction of existing buildings for any new construction.

Both the Nasrid dynasty and the Roman popes were rulers in secular and sacred realms and used symbols from both worlds to legitimate their claims to power and authority. The walls inside the Alhambra are filled with inscriptions of Quranic verses and panegyric poetry singing the many praises of the Nasrid dynasty. At the Palace of the Popes, the court ceremonies that had evolved over hundreds of years, the grandiose styles of architecture, and the many works of art commissioned to decorate the rooms gave an aura of grandeur designed to assist an embattled papacy to legitimate its long-term residence outside Rome. In both cases, the intention was to project a necessary image of power and authority to those around the ruler, whether in the court itself or throughout their respective empires.

The Alhambra fits well within a building tradition in the Islamic world dating back centuries. However, palace-cities were not typical architecture in medieval Europe, and the Palace

➤ INSCRIPTIONS AT THE ALHAMBRA

Calligraphy is an important art form in the Islamic world and has been used to decorate architecture dating back to the eleventh century. Three types of inscriptions are included on the walls of the Alhambra: verses from the Quran, mottoes, and original poetry.

Quranic verses are found in prominent locations such as in the Hall of the Ambassadors, the main reception hall at the Alhambra, or on the entrance gate leading from the royal quarter to the *madina*, or common area. Repetitive inscriptions can be found in prominent public places too, such as the motto of the dynasty, “There is no Victorious One except God,” which is often decorated with a border that makes for a kind of shield or coat of arms found throughout the palace-city. Lastly, original poems by important government officials sing the praises of the dynasty but also demonstrate the values of a tiny kingdom on the far edge of the Islamic world anxious to identify with its Muslim counterparts in the East. All such inscriptions were used to emphasize Nasrid power and authority in both sacred and secular contexts.

—April L. Najjaj

of the Popes has so many similarities with the Alhambra only because it is a European anomaly. With both sites, the loss of their greatest purpose—as a permanent residence for their respective dynasties—signaled their downfall, for the last pope to live in Avignon escaped in the middle of the night in 1403, and the Alhambra was surrendered to the Christians in 1492.

An additional coincidence between the Alhambra and the Palace of the Popes is their survival to the present day. Both were extensively damaged in the decades after the fifteenth century, suffering from wars, fires, natural disasters, and misuse over time. Although renovations were done in the sixteenth and seventeenth centuries, any such efforts ended with the onset of the Napoleonic wars when both sites were occupied by French troops. Only into the early twentieth century have large-scale efforts been carried out to restore and preserve these sites for their historical significance and tourism revenues.

Cairo and Acre—Capitals of Two Cultures in Conflict

When Latin crusaders seized control of a narrow strip of territory along the eastern shore of the Mediterranean around the turn of the eleventh century, they found themselves in a relatively urbanized environment. Although the new Western rulers of Outremer, “the land beyond the sea,” altered urban topographies in a strictly local sense, they did not, overall, transform the physical environments in which they were now living. Instead, there was a process whereby the new residents of the Levant acculturated to their new homelands.

The walls of cities such as Antioch and Jerusalem initially stood as obstacles to the crusader armies. Once captured, however, the fortified cities of the Latin East offered the nascent states both protection and economic opportunities. The Westerners improved upon defensive structures and learned how to construct new ones from extant buildings. They brokered trade deals

and found themselves immersed in both the Mediterranean and overland trade of the Levant. Governing such locales—filled with what seemed to them to be exotic languages, customs, and religions—proved complex. Frankish traditions of rule overlapped with Eastern Mediterranean (whether Islamic or Christian) norms. Acre, just one of the cities now part of the Latin East, emerged as their most populous and prosperous port. Jerusalem provided the initial political and religious capital, but its distance from the sea ensured a relatively marginal economic stature. Once Jerusalem fell in 1187, Acre gained the political prominence to match its already vibrant economy.

Even as Acre became more important, political authority in the city trended toward decentralization. Immediately after its conquest in 1104, the Genoese, in exchange for their naval support during the siege, claimed a section of the city to operate as their own merchant colony. Pisa and Venice, Genoa’s rivals, also managed to obtain their own quarters eventually. Later, as the military orders gained in prominence, they too were granted possession of fortified dwellings or permission to construct new ones. Other important nobles were granted houses, churches, and other important sites to expand upon and improve as they wished. Furthermore, those who had a stake in Acre were constantly seeking to acquire more territory within the walls. Less studied, Acre depended on trade with the agricultural hinterland and Islamic sites farther to the east, and those involved with the overland trade also required secure and reliable housing and services within Acre. This city lacked a single central market, instead operating with as many as a dozen commercial focal points.

Acre was lost in 1187, as was Jerusalem, but the former was reclaimed in 1191. With the holy city remaining in Islamic hands, Acre became the capital of the kingdom of Jerusalem. If anything, the political role only accelerated existing trends of increased mercantile activity and the decentralization of urban power. It became more critical for every powerful faction to gain a foothold in the city and to keep others from becoming too dominant. For example, after 1191 the new Teutonic Knights gained a tower, and merchants from Marseilles acquired a quarter.

Walls of Acre, probably of Mamluk or Ottoman construction. The Muslim-controlled city of Acre was besieged by Christians during the Third Crusade. Acre fell in July, 1191 after a siege of 23 months, led by Richard the Lionhearted of England and Philip II of France. (Alfred J. Andrea)

➤ IBN JUBAYR'S OBSERVATIONS ON ACRE AND CAIRO

Abu l-Husayn Muhammad ibn Ahmad ibn Jubayr, secretary to the governor of Granada, left his home in 1183 in order to make a pilgrimage to Mecca. En route he stopped in Cairo and recorded his observations. Although he wrote most extensively on Cairo's shrines dedicated to holy men, Ibn Jubayr also noted the improvements to Cairo's infrastructure being undertaken at Saladin's orders. He saw workers cannibalizing blocks of stone from older walls for the various projects. He stopped in diverse villages in the city's hinterlands, noting that he found them both prosperous and hospitable. He praised the new citadel as an "impregnable fortress," built by "foreign Rumi [Roman] prisoners whose numbers were beyond computation." The author sought to present Saladin as a great builder who did not force Muslims into hard labor.

After completing his hajj, Ibn Jubayr stopped in Acre to obtain passage on a ship headed west and home. One must weigh the author's reported experiences against the angry rhetoric he unleashed against the city's current rulers. "Unbelief and unpiousness there burn fiercely," he wrote,

"and pigs and crosses abound. It stinks and is filthy, being full of refuse and excrement." But then the author admitted that one mosque remained in Muslim hands, providing refuge for travelers just like him. The wells were plentiful and the city was rich, in part because of its trade with nearby Muslim-held Damascus. Finally, the worldly traveler found extraordinary beauty in the city, writing that "at the eastern extremity of Acre is a torrent course, along the banks of which extending to the sea is a sandy plain, than which I have seen no more beautiful sight." Soldiers paraded on horseback along this course daily, and the author found the spectacle enjoyable to watch, even though he felt it was necessary to add to the description of the Christian knights "Destroy them, God."

Ibn Jubayr, *The Travels of Ibn Jubayr*, translated by R. J. C. Broadhurst (London: Jonathan Cape, 1952), 43, 318, and 325.

The division of the city did not, according to the research of David Jacoby, result in a wholesale transformation of the spatial arrangements of the preexisting Syrian site. The fortifications were definitely improved both in the early twelfth century and again when Louis IX (r. 1226–1270) of France, fresh from his humiliating captivity in Egypt, tried to salve his pride by spending lavishly on Acre. Other than that, the Latin rulers kept the city's buildings operating in largely the same function as they were before 1104. Mosques frequently became churches, but the sacred landscape remained roughly the same structurally. Markets, bakeries, and bathhouses continued to provide a place to buy and sell, to acquire one's daily bread, or to wash. The old harbor provided ample space for even the greatly accelerated pace of trade under Latin rule and was not expanded upon. New buildings were put up, but these usually aped the structure and function of those already extant. In the long run, the history of crusader Acre provides a case of Latin

adaptation to the norms and physical realities of urban life in the Levant.

The presence of crusaders in Outremer resulted in changes to Muslim-held cities, however. As the balance of power and the tides of trade shifted, Cairo became one of the great capitals of the Islamic world. At the onset of the crusades, Egypt was ruled by the Shia Fatimids, who were threatened by the ever-expanding Seljuk Turks. Although a great city, Fatimid Cairo existed on the periphery of a Sunni Muslim world that focused on places such as Damascus and Baghdad. Multiple factors intervened to change Cairo's relative status, including the collapse of the Fatimids in 1171, the presence of a crusader buffer between Egypt and the Seljuks (and the Abbasids), the rise of Saladin in Egypt, the thirteenth-century destruction of potential rivals by the Mongols, and finally the emergence of the Mamluks.

During the first few decades of the twelfth century, internal weaknesses in Egypt resulted

in the territory becoming a prize in a contest among various Christian and Islamic factions. Saladin (1138–1193) ultimately won control and used Egypt as a staging area for his agenda in Syria. He considered Cairo a potential capital for his empire and began to alter the city to make it suitable for such a purpose by building a massive citadel in the heart of the city. This building, he hoped, would be a symbol of his power to awe his subjects. Among those who built the citadel were Frankish slaves, numbering as many as 50,000 according to one Arabic source. In comparison to Acre, Cairo's history contains a very different way that the presence of crusaders altered the shape of an Eastern Mediterranean city.

It is under the Mamluks that Cairo truly came into its own. The Mamluks, originally Central Asian slave-soldiers, staged a coup in 1250. Once they had stabilized their new sultanate, the Mamluk leaders began to pay attention to the newfound capital city. Baibars al-Bunduqdari (r. 1260–1277) expanded on the citadel by adding a great mosque, as grand as any in West Asia. Qalawun al-Alfi (1279–1290), his successor, built a grand madrasa and hospital next to the site where he eventually was entombed. Elite Mamluks sought to elevate their culture by patronizing the arts and intellectual life. As the Mongol advance stalled and the Latin fortifications of Outremer became either forgotten relics or repurposed possessions of the victorious Muslims, Cairo and the Mamluk empire emerged as a new center of Islamic life, and Acre, which the Mamluks captured and leveled in 1291, became a ghost town.

Byzantine Constantinople

The ancient Greek merchant city of Byzantion (later Latinized to Byzantium) suddenly became the capital of the Roman empire in 330 CE, when the emperor Constantine I (r. 306–337) founded the city eponymously known as Constantinopolis (the City of Constantine). According to myth, Byzas of Megara originally founded the city around 668 BCE after consulting the Oracle of Apollo in Delphi for the best location. Its location on the narrow Bosphorus Strait that connects the Sea of Marmara with the Black Sea proved ideal, and the village quickly prospered into an important economic bridge between East and West.

With the natural harbor of the Golden Horn to the north and east, the Bosphorus Strait along the narrow tip of its eastern shore, and the Sea of Marmara to the south and west, Constantinople was accessible by land on only one side. To defend this approach, the prefect (*exarch* in Greek) of the East, Anthemius, supervised construction of massive defensive walls, known as the Theodosian Walls inasmuch as they were constructed during the reign of Theodosius II (r. 408–450). About four miles (6.5 kilometers) in length, including the adjoining Blachernae walls, they spanned the peninsula. Initially constructed with two parallel perimeters, with a third and lowest perimeter wall (about 5.5 feet or 1.7 meters high) added later, as well as various towers, fortresses, and reinforcements, the triple-tiered land walls varied in thickness: 1 foot (0.3 meters) for the outermost, or screen, wall; 6 feet (1.8 meters) for the second wall; and up to 20 feet (6 meters) in places for the innermost wall. The inner wall stood 40 feet (12 meters) high with towers located every 180 feet (55 meters), each of which stood 66 feet (20 meters) tall. The walls of Constantinople, which also included many miles of seawalls along its three other sides, repulsed numerous sieges over the centuries. On April 12, 1204, however, soldiers and sailors of the Fourth Crusade managed to successfully storm the lesser sea walls that faced the Golden Horn. For the first time in its history the city was captured by direct assault, mainly because recent emperors had not made adequate

► CONSTANTINOPLE DURING THE LATIN EMPIRE

When the soldiers and sailors of the Fourth Crusade captured Constantinople in 1204, they took over a city that had suffered three devastating fires that various crusader contingents had set between July 17, 1203, and April 13, 1204. Major portions of the heart of the city lay in ruin, and a substantial number of inhabitants fled the city as a result of the fires and the Latin conquest. Moreover, the conquerors set in motion a series of events that ultimately reduced the overall wealth and stability of the city. In part this was due to their pillaging of many of the city's treasures during their half century of occupation. In larger part it was due to the fact that the Latin emperors and their underlings did not comprehend, appreciate, or possess the level of engineering technology or administrative expertise necessary to maintain the city.

The Western conquerors divided the city into Frankish and Venetian spheres of sovereignty, with the Frankish Latin emperor receiving five-eighths of the city and the Venetians three-eighths (prime commercial territory along the harbor of the Golden Horn). There were several reasons for this division, but one was ignorance of the interconnected system of taxes, communication, and supply that the empire and a city as large as Constantinople required. In particular, the water supply system required regular maintenance from a large workforce. This required a degree of technical coordination and financing that only a centralized and professional bureaucracy could

manage. The overall size of the city and its diverse functions only intensified the need for a centralized administration and experienced personnel, both of which were in short supply even though some Byzantine officials remained behind to serve their new Latin masters. However, the Latin emperors and their Western deputies imposed a feudal system of patronage and fealty that proved incompatible with the imperial system and hence unable to perform properly the city's administrative and engineering requirements. Consequently, much of the city fell into ruin, especially the imperial five-eighths of the city.

Although the Venetian section of the city suffered from this breakdown of the former city-wide administration, on balance it prospered due to Venetian commercial acumen and its favorable harbor-side location, which had not been gravely affected by the fires. Nevertheless, despite Venetian success with maritime commerce, their activity was primarily a process of wealth extraction, not investment. Consequently, even the harbors suffered neglect and did not receive the regular maintenance they required. Although the Latins occupied Constantinople for only 57 years, the fragmented and largely neglected city they left behind would never regain its former glory, although Byzantium itself would undergo a religious, artistic, and literary renaissance during the two centuries of life left to it.

—George N. Lundskow

preparations. Almost invincible when properly garrisoned, the city's land walls failed only once, in 1453, when the Ottomans succeeded in breaching them with heavy cannon fire. Even so, the Turks still required two months of bombardment to blast the walls open sufficiently to storm the city.

The local environment contributed to security as well because the prevailing winds from west to east across the Golden Horn, in conjunction with the tides, made unwanted access into the harbor extremely difficult. The Byzantines also stretched a massive chain across the 600-foot- (183-meter-) wide entrance to further inhibit unwanted ships, although the Venetians

managed to break the chain and enter the harbor in 1203.

Relatively fertile with moderate temperatures, the area inside the walls amounted to about 40 square miles (100 square kilometers). This compares to 48.4 square miles (125 square kilometers) for present-day Boston, Massachusetts. In medieval Constantinople much of the area was undeveloped, as the distance from the Golden Gate in the Theodosian Walls to the city center (the Augusteum) was about 6.5 miles (10.5 kilometers). This undeveloped land and advantageous growing conditions meant that the city could feed itself adequately during prolonged sieges.

Section of the Theodosian walls of Constantinople that still stands today in present-day suburban Istanbul. These land walls were built in the fifth century by Emperor Theodosius II. The land and sea walls of the city withstood all but two invasions in 1,600 years: the Fourth Crusade in 1204 and the conquest of Mehmed II in 1453. (iStockPhoto.com)

Yet the city's location also required a high degree of engineering infrastructure in order to survive and prosper. Water in particular proved one of the greatest challenges, and this challenge was met through a system of aqueducts and cisterns. The remains of the aqueduct of the emperor Valens (r. 364–378), which brought water from the Belgrade Forest about 12 miles (20 kilometers) northwest, can still be seen. Other aqueducts built during the reign of Justinian I (r. 527–565) greatly expanded the system, which supplied water to several hundred underground cisterns, the largest of which held about 21 million gallons (80 million liters). Also built in the reign of Justinian I was the Basilica Cistern, which resembles an underground palace with numerous vertical marble columns, Corinthian-style pedestals, vaulted ceilings, and brick walls covered with Roman concrete. Today it is a popular tourist attraction.

Rebuilding Constantinople

On May 29, 1453, the city of Constantinople fell to the Ottoman Turks, thereby ending the Byzantine empire. When the Ottomans finally entered this highly symbolic capital, they found a city that had been on the decline for some time. In 1453 the population of Constantinople was estimated to be 30,000–40,000. Sultan Mehmed II wanted to move his capital from Edirne to Constantinople in order to lay claim to its various historical legacies, which would convey imperial legitimacy and allow the Ottomans to assert their claim to the lands of the Roman empire. Yet the city was no longer powerful or prosperous; Mehmed II immediately set to work to rebuild the city, which was to become the jewel of the empire.

Constantinople, even in its reduced state, was too big for a single center, so many neighborhoods were created to help inspire growth. The focus of each neighborhood was usually a mosque complex that served its religious, educational, social, and economic needs. These complexes often included soup kitchens, schools, public baths, hospitals, markets, and inns in addition to the mosque proper. To set an example, Mehmed II—or Fatih ("the Conqueror")—built an eponymous complex, which was to be the largest in the empire, to contribute to the restoration of city life. This Fatih Camii, or Conqueror's Mosque, was constructed on the site of the demolished Church of the Holy Apostles, the second greatest church in the former Byzantine empire (after Hagia Sophia) and the place of burial for many of Byzantium's emperors. Mehmed's own tomb was later incorporated into the new mosque's complex. Most other Byzantine churches, such as Hagia Sophia, were converted to neighborhood mosques.

The physical reconstruction of the city had many aspects. Militarily, the city walls needed to be repaired and refortified. Since the city was the new capital, the sultan also needed a palace. He built two: the Forum Tauri (also called Eski Saray), finished 1455, and Topkapı Palace, begun 1459. The construction of covered markets, such

➤ A CONTEMPORARY DESCRIPTION OF MEHMED II'S REBUILDING PROJECTS

Michael Kritoboulos (ca. 1410–1470), better known simply as Kritovoulos, a Greek from the island of Imbros, came into the service of the sultan after the siege of Constantinople and wrote a biography that depicted the conqueror as a hero. Kritovoulos had great respect for the sultan's military prowess and governing abilities.

In his work, Kritovoulos describes Mehmed II's efforts to rebuild and repopulate Constantinople:

"He [Mehmed II] repaired the damaged walls—from cannon or time—and he also laid the foundations of the royal palace. . . .

And he commanded them to construct a very large and very fine marketplace. . . .

He also ordered them to construct splendid and costly baths, and through aqueducts to bring into the City from the countryside an abundance of water. Many other such things he ordered to be

done for the building up and beautifying of the City, and for the benefit and needs and comfort of the inhabitants.

Above all he was solicitous to work for the repopling of the City and to fill it with inhabitants as it had previously been. He gathered them there from all parts of Asia and Europe, and he transferred them with all possible care and speed, people of all nations. . . . So profound was the passion that came into his soul for the City and its peopling, and for bringing it back to its former prosperity."

—Katie L. Johnson

Kritovoulos, *The History of Mehmed the Conqueror*, translated by Charles T. Riggs (Westport, CT: Greenwood, 1970), Part 2, paragraph 2, pp. 54–56.

as the Grand Bazaar that opened in the heart of the city in 1461, and other commercial centers revived the economic life of the city.

While these building projects helped to create an infrastructure, the city still needed people. The conquest of the city had caused many of its inhabitants to flee; the rest were enslaved. Mehmed II settled his share (one-fifth) of the enslaved Greeks in what is now Fener, where they were granted houses and religious privileges and were even tax-exempt for a time. This policy was supposed to inspire those who had fled to return; they were promised houses, land to reestablish themselves, and freedom of religion and work. Jews who had remained in the city were granted their own quarter (Balat); they were soon joined by many other Jews, most of them coming from Europe, especially those who had been expelled from Spain.

Additionally, a state-controlled resettlement policy was put into effect. Newly conquered cities sent families, especially artisans and merchants, to the new capital. From the Ottoman lands, more than 5,000 families—Muslims, Jews, and Christians—were required to relocate to Constantinople. Opposition to the deportations slowed this process, which was never fully real-

ized. In order to support the growing capital, approximately 30,000 peasants from the Balkans were settled in villages around Constantinople.

By the end of Mehmed II's reign, Constantinople was thriving. According to the 1477 census, the population had nearly doubled to 80,000–100,000 people (16,324 families). By the early sixteenth century, Constantinople had grown to 400,000 people. Mehmed II's efforts to rebuild and repopulate the city dominated his reign, and his success can be seen throughout the subsequent centuries.

Karakorum and Dadu—Two Mongol Capital Cities

In describing the Mongols, Friar John of Pian de Carpini (Plano Carpini) said that they did not build villages or cities with the exception of their capital of Karakorum. The area around Karakorum (Qaraqorem) was originally acquired early in the thirteenth century by Chinggis Khan when he defeated the Naimans, a competing Turko-Mongol confederation. The site lay on a broad plain in the Orkhon Valley with ample water and grazing. It was protected on all sides by hills and was possibly used by Chinggis as a base camp.

Mongols indigenous to the steppe did not build villages or cities because they were pastoral nomads. This is reflected in their indigenous dwellings called *gers*, more commonly known by their Turkic-Russian name *yurts*. The *ger* is designed for mobility. It has walls of collapsible wooden lattice and a roof of poles that radiate from a center ring. The ring is sometimes supported by two decorated center posts. Once the frame has been erected it is covered with a thick blanket of felt, which keeps the *ger* warm and comfortable even in the winter. Gers could also be built on a cart and pulled by oxen or yaks from place to place, perhaps the first truly mobile home.

A stone tortoise sculpture marks the location of Karakorum, Chinggis Khan's capital in Mongolia. Near the sculpture, stupas stand along the wall surrounding the abandoned Buddhist Erdeni Dzuu lamasery. (Dean Conger/Corbis)

In 1235 Ögedei, successor to Chinggis Khan, began the construction of a permanent capital at Karakorum. The area for the capital was enclosed by a wall, and in the tradition of the Chinese the palaces and their gardens were surrounded by a wall to divide them from the rest of the city. The buildings inside the inner wall represented a mix of styles. Diagrams from Russian excavations in the 1940s show some large buildings with rounded corners, possibly gers. The largest was a place for assembly and audiences called the Great Ger, which could hold large numbers of people. The palace and private apartments were long and rectangular and seem to follow Chinese or Jurchen (also Ruzhen or Nuzhen) architectural style.

William of Rubrick visited Karakorum in the 1250s but was unimpressed. He compared the Mongol capital to the village of St. Denis outside Paris, noting that Karakorum was not as important as St. Denis and that the monastery of Saint-Denis was worth twice the amount of the palace of the khan. He also mentioned there was a Nestorian (Assyrian Christian) church at Karakorum, which he described as “large and beautiful, being entirely covered with silken cloths embroidered with gold.”

As they advanced though northern China and Central Asia the Mongols captured skilled workers, who were taken back to Karakorum to help with the building and to populate the city. Nearly 30,000 artisans were taken from Bukhara and Samarkand (both in present-day Uzbekistan) and shipped back to Karakorum. Karakorum remained the capital of the Mongol empire until 1264, but nothing remains of it today except some stone turtles that marked the boundaries. The city's ruins were stripped in the sixteenth century to provide materials to build a nearby Buddhist monastery.

As the Mongols moved eastward they gained control of the Tangut and Jurchen kingdoms of northern China. In 1264 Khubilai Khan shifted the Mongol imperial capital from Karakorum to an area within present-day Beijing, which he renamed Daidu (Great Capital) and the Chinese called Dadu. To many visitors from afar who were awed by it, it was also known by its Turkic name, Khanbalik (City of the Khan). Three years later, building began on a Mongol capital of Chi-

nese design on Chinese soil. Khubilai chose a Muslim architect, but the plans for the new capital were drawn from an ancient Chinese classic on government, the *Zhouli* (*The Rites of the Zhou Dynasty*). A wall of rammed earth roughly 17 miles (27 kilometers) in circumference surrounded the city. Wide avenues were laid out on symmetrical north-south and east-west axes. The wall had 11 gates, each of which had a three-story sentry tower. Inside of the outer wall were two interior walls surrounding the Imperial City and the Great Khan's palaces where Khubilai and his entourage lived. Officials lived outside the Imperial City but within the second set of inner walls. Ordinary Mongols and Chinese lived outside the city. The Imperial City contained many important buildings, including a hall for receiving ambassadors, the khan's palace, and the living quarters of his consorts and concubines as well as storehouses and a Scholar's Hall, which served as a school for the young princes. The Imperial City was landscaped with gardens, parks, lakes, and streams, the latter of which were crossed by decorative bridges of Chinese design. In appearance Dadu resembled typical Chinese capitals of earlier dynasties, although there were a few Mongol elements.

To remind him of his origin, Khubilai had a patch of steppe grass planted in the palace garden. Some gers were also erected in the imperial parks, where many of the khan's sons and relatives lived. When an imperial wife was about to give birth she was moved into a ger so that the birth took place in a Mongol dwelling. Other Mongol touches were the ermine-skin screens in the imperial sleeping quarters, but for the most part the decorative motifs throughout the palaces were Chinese.

To placate the Confucian elite, Khubilai Khan instituted some Chinese court rituals, and several traditional Chinese and Tibetan temples were built near the palaces. One of the most important was the Great Temple (also known as the Ancestral Temple), which carried on Chinese rituals of ancestor veneration. However, the Chinese designs and the concessions to the Chinese angered many Mongols, who viewed the lifestyle at Dadu as decadent and contributing to the increasing weakening of the Mongol rulers. Moreover, many Chinese, especially Confucian scholars,

> A PERSIAN VIEW OF THE MONGOL CAPITAL OF DADU

In the fourteenth century the Persian historian Abdullah bin Fazl-ullah of Shiraz, under the pseudonym Wassaf (the Describer), wrote about his travels to the Mongol court. In the following excerpt of his *Tarikh-i Wassaf* he describes the Mongol capital of Dadu.

"[Khubilai Khan] called the city Dadu [Chinese for 'Great City']. He commanded that artisans and craftsmen should be brought from all directions to this city. Because of the number of its inhabitants and the milling crowds, this city in a short time became a place of assembly resplendent and ornamented overall. On one side of this city he built . . . the throne of rule and khanship. . . . It was built of wood and planks, and was also square with each of its sides four hundred paces long. This elysian structure was endowed with a cupola and windows, putting to shame the pinnacles of the celestial tabernacle, with solid pillars richly decorated and embellished with ornament. The floor was inlaid with jasper. Statues were set up and pictures painted, with both art and wit, radiating talismanic art. Archimedes would have been astonished and baffled by these delicate combinations and Euclidean inventions; the grills in front of the windows were made of gold and silver, and above the pinnacles of the canopy the moon in its three stations . . . trembles with jealousy. [It brings to mind] a quotation: 'The many-columned city of Iram, whose like has never been built in the whole land' [Quran 89:7,8]. Anybody who saw the creations in this place and the beauty of this treasure: 'saw how Spring and the bejeweled fields, just as the hill and the mountain, bowed down.'"

refused to acknowledge the legitimacy of Mongol rule despite these concessions.

Dadu did not survive the Yuan dynasty. In 1368 Zhu Yuanzhang (Taizu), the founder of the Ming dynasty, captured Dadu and burned it to the ground, establishing his capital at Nanjing (Southern Capital). In 1421, however, the Yongle emperor, the third Ming ruler of China, moved the primary imperial capital back to the north, to Beiping (Northern Peace), later renamed Beijing (Northern Capital). Here, as early as 1406 construction had begun on the so-called Imperial Forbidden City, just south of the ruins of Dadu. Although almost no Yuan imperial structures had been left standing from Dadu, its parks and lakes remained and were incorporated into the Ming capital. The popular Beihai Park in the heart of modern Beijing is one of the few remnants left to be seen of Khubilai Khan's Imperial City.

Angkor and Angkor Wat

Angkor Wat, a temple complex dedicated to the Hindu deity Vishnu, was built in the twelfth century CE in the ancient city of Angkor, 192 miles (310 kilometers) northwest of Phnom Penh. It is probably the largest (and, as many have claimed, the most beautiful) religious monument ever constructed. Certainly it is the most famous of all Khmer temples.

Angkor served as the capital of the Khmer empire of Cambodia from 802 until 1295. Evidence uncovered since 1996 has led some scholars to assert that the site may have been occupied some 300 years earlier than first thought, obviously affecting accepted chronologies. Whatever the case, its powerful kings held sway from what is now southern Vietnam to Yunnan, China, and westward from Vietnam to the Bay of Bengal. The

city site was probably chosen for strategic reasons and for the agricultural potential of the region. Khmer civilization was at its height between 879 and 1191, and as a result of several ambitious construction projects, Angkor eventually grew into a huge administrative and social center stretching north to south for 8 miles (13 kilometers) and east to west for 15 miles (24 kilometers). The population possibly reached 1 million.

Apart from the hundreds of buildings—temples, schools, hospitals, and houses—there was an extensive system of reservoirs and waterways. The public and domestic buildings, all of timber, have long since decayed. But because they were the only structures in which masonry was permitted, over 100 temple sites survive. Earlier examples were mostly of brick, but later, the porous, iron-bearing material known as laterite was used, and still later sandstone, quarried about 25 miles (40 kilometers) away.

The city of Angkor was the cult center of the Khmer Devaraja, the “god-king,” and an important pilgrimage destination. Khmer kings, from Jayavarman II (802–850) onward, had come to be worshiped as gods, and the temples they built were regarded as not only earthly structures but as symbols of Mount Meru, the cosmological home of the Hindu deities. The official state religion was worship of the Shiva Lingam, a pillar representing the power of the Hindu god Shiva that also signified the king's divine authority. Jayavarman II had identified kingship with Shiva, and acting upon that precedent, King Suryavarman II (1113–ca. 1150) presented himself as an incarnation of the god Vishnu. He built Angkor Wat as a temple and administrative center for his empire and as his own sepulcher (which is why it faces west).

Financed by the spoils of war and taking over thirty years to finish, the sandstone-and-laterite Angkor Wat occupies a 2,800-by-3,800-foot (850-by-1,000-meter) rectangular site. Its layout provides an architectural allegory of the Hindu cosmology. The temple is surrounded by a 590-foot-wide (180-meter) moat, over 3 miles (5 kilometers) long, which represents the primordial ocean. A causeway decorated with carvings of the divine serpents leads to a 617-foot-long (188-meter) bridge that gives access to the most important of four gates. The temple is reached

by passing through three galleries separated by paved walkways. It is an approximately pyramidal series of terraces and small buildings arranged in three ascending stories—they stand for the mountains that encompass the world—and surmounted at the center by a temple “mountain” of five lotus-shaped towers, symbolizing the five peaks of Mount Meru. Four of the original nine towers have succumbed to time and weather. The temple walls are replete with wonderfully crafted bas-reliefs, many of which were once painted and gilded, including about 1,700 heavenly nymphs and others that depict scenes of Khmer daily life, episodes from the epics *Ramayana* and *Mahabharata*, the exploits of Vishnu and Shiva, and (of course) the heroic deeds of King Suryavarman II.

In 1177 Angkor fell to the Cham army from northern Cambodia, which held it until it was retaken early in the reign of the Khmer King Jayavarman VII (r. 1181–ca. 1215). When he built Angkor Thom nearby he dedicated his new capital to Buddhism, and Angkor Wat became a Buddhist shrine. Many of its carvings and statues of Hindu deities were replaced by Buddhist art. The Thais sacked Angkor in 1431. The following year the Khmers abandoned the city, and it was left to the encroaching jungle for a few centuries. However, Theravada Buddhist monks kept Angkor Wat as intact as possible until the late nineteenth century, making it one of the most important pilgrimage destinations in Southeast Asia.

Europe’s Urban Revolution, 1000–1300

Although Western Europe was still an overwhelmingly agrarian society with the majority

Panel painting of an idealized city on the sea by Ambrogio Lorenzetti, early fourteenth century. (Scala/Art Resource, NY)

of its population living in small villages, its towns and cities realized substantial growth from about 1000 to around 1300, a growth that was driven by a dramatic revival of trade and the emergence of specialized artisans and that, in turn, contributed to a further quickening of Europe’s economic pace.

Newly expanded cities grew from two sources. First, towns that had been ancient Roman *civitates* (municipalities) still existed, often as the seats of power of bishops and feudal lords, although they were significantly smaller in size and population than their Roman forerunners had been. Production and commerce never totally disappeared in Europe after the collapse of Roman order in the western half of the empire, but after about 950, both underwent a decided upswing. Consequently, during the eleventh and twelfth centuries merchants began to settle in these towns in increasing numbers, followed by craftspeople, often from nearby manors, who recognized an opportunity to sell or trade their goods to merchants who, in turn, sold them in the wider market. Second, from the late tenth century on, new cities and towns were founded, especially in northern Europe. In this instance, it was generally merchants who founded these new towns, often near a fortified stronghold such as a castle or monastery that was close to a major trade route, preferably a water route. The merchants could take refuge in case of attack within the walls of the fortification, and over

➤ PARIS AND FLORENCE—A STUDY IN CONTRASTS

A comparative examination of Paris and Florence in the late thirteenth century highlights several important differences among the cities of medieval Europe. Paris was the capital of the French monarchy, which was strengthening its power throughout the royal domain by extending the machinery of royal government from Paris into the provinces and subordinating feudal nobles to royal control. An ever-expanding royal bureaucracy in Paris oversaw matters such as finance and royal justice. Furthermore, the city was the site of the great University of Paris, renowned throughout Europe for its theological faculty. In preparation for careers in ecclesiastical or secular government, students from all regions of Europe came to Paris to study, thereby swelling the population and adding a distinctly international flavor to the university quarter of the city on the Left Bank of the Seine River. The Left Bank also held the monasteries of St. Genevieve and St. Germain des Prés. The heart of the city, the *Île de la Cité*, housed the royal residence, the great Gothic cathedral of Notre Dame de Paris, the bishop's palace, and residences of other clergy. In Paris, as in most northern cities, nobles usually did not live in the cities, although Paris had two great royal castles, the Louvre and the Bastille.

In Italy, by contrast, nobles often held urban fortified residences, and their distinctive urban

towers were a distinguishing feature of the urban landscape. Florence, like other cities in northern and central Italy, was a self-governing city-state, encompassing the urban area and the surrounding countryside (or *contado*), without the overlordship of an emperor or king. In Florence governmental power rested in the hands of the guilds, creating a merchant oligarchy, although Florence referred to itself as a republic. The twin pillars of the Florentine economy were the enterprises of banking and textile manufacturing. Florentine banks handled the financial activities of the papacy, and over time Florentine banks, especially the Bardi and Peruzzi banks, became the most influential in Europe, even loaning money to monarchs. Florentine coinage, the gold florin, became the international currency of Europe. Florence boasted the most extensive wool manufacturing in Europe. Wool workers at all levels were members of guilds, which were designated as either major or lesser guilds (*arti maggiori* or *arti minori*, respectively). Like Paris, Florence was also an episcopal seat, but unlike its French counterpart, the Florentine cathedral, or *Duomo*, was not built in the Gothic architectural style, which never gained widespread popularity in Italy, but rather reflects the emerging style of the Italian Renaissance.

—Jan K. Bulman

time if the settlement took root and prospered, walls enclosing the new settlement were added and then expanded.

Cities often were subject to a lord's jurisdiction, and lords tended to regard their cities in the same way they regarded their serfs and vassals. Nonetheless, over time merchants, who required mobility to engage in trade, began to demand liberties that were not available to them as subjects of a lord. Lords, in turn, saw that townspeople were willing to pay for privileges, such as the right to control property, freedom from military obligations to their lord, the right to choose their own governing officials and to administer their own courts, and written charters guaranteeing these liberties. These rights and charters generated a new substantial source of income for lords and guaranteed the

townspeople, or at least the merchant oligarchs who secured these charters, a measure of self-government and permanence as a recognized corporation.

European cities were quite small when compared to their ancient predecessors or to their contemporaries in other parts of the world, such as Constantinople, Cairo, Baghdad, or Hangzhou. For example, thirteenth-century London, the largest city in England, had a population of about 30,000. Trading centers such as Bruges and Ghent, both in Flanders, had populations of about 40,000. In Italy, where cities had never shrunk in size, number, and importance to the extent that they had in northern Europe, urban populations were larger, with Venice, Florence, and Milan each boasting about 100,000 people before the mid-fourteenth century.

The surrounding countryside provided the food to support city inhabitants, so rural and urban spheres were closely connected. As cities grew, their walls often became constricting, creating competition for space within the urban landscape. Streets were narrow and winding, buildings crowded against one another, and second or third stories loomed over confined streets. In many medieval towns, the most substantial buildings were the churches, and if the town was an episcopal city, the cathedral dominated all other structures, including houses, taverns, and collegiate and parish churches. Most medieval cities were divided into sections or neighborhoods in which a particular trade dominated. Fire was a constant threat since most buildings were constructed of wood. Pollution was a constant fact of life. Human and animal waste was dumped into the streets, the air was choked with smoke from wood and coal fires, and rivers were soiled from the refuse that butchers, tanners, and other workers dumped into the waters.

Beginning in the late twelfth century, first merchants and then those who worked in particular urban industries, such as textile manufacture, metalworking, the production of leather goods, etc., began to form organizations called guilds. By the thirteenth century there was a guild dedicated to almost every craft, from tanners and bakers to more specialized groups such as silk merchants, notaries, and spice traders. In the cloth industry, guilds represented each process of the manufacturing process, such as spinning, weaving, fulling, and dyeing. Guilds oversaw nearly every occupational aspect; they established product standards and prices, workers' wages, and the maximum number of occupational practitioners allowed in the town or city. Furthermore, guilds also had social functions; they buried their members, took care of the widows and orphans of the membership, and sponsored religious festivals. Women were sometimes members of guilds, especially as widows if they had worked with their husbands in a particular craft and continued in that work following the husband's death. Female workers dominated certain aspects of textile manufacturing such as spinning silk, which was also reflected in their guild membership. Because guilds were associated with manufacturing and crafts,

they dominated medieval urban life where these occupations were most evident.

Urban residents constituted a small minority of Europe's total population, but because the towns and cities they inhabited were centers of commerce and industry, the wealth that they generated made them an important catalyst in the economic revival of Europe. Although beginning in the mid-fourteenth century cities and towns would experience sharp declines in population in the wake of the Black Death, in general their influence and importance continued to grow throughout the Middle Ages and beyond.

Tenochtitlan

The capital city of the Mexica (Aztec) empire, Tenochtitlan was founded in 1325 CE and fell to the Spaniards under Hernando Cortés on August 13, 1521. In less than 200 years, the island city had a remarkable growth and development, and by the time the Spaniards arrived it was one of the largest cities in the world. Certainly, it was one of the most beautiful: the Spaniards were in awe of it as they gazed upon the city shortly before meeting the Aztec emperor Motecuhzoma (Montezuma).

According to legend, Tenochtitlan was founded at a nadir in Aztec history. The Aztecs had just been driven out of a city where they had served as mercenaries, having committed atrocities that disgusted their hosts. The Aztecs were forced to flee to a group of low, swampy islands that lay in the western part of Lake Texcoco, the largest of a series of lakes that formed

the heart of the basin of Mexico where Mexico City now stands. It had long been prophesied that they would be given a divine sign by their patron god, Huitzilopochtli, when the time was right to build their city and become ancient Mexico's "chosen people." This sign would be an eagle eating a snake and perched on a prickly-pear cactus, and the Aztec priests saw that sign on those swampy islands in Lake Texcoco.

The Aztecs settled on the islands, driving wooden stakes into the grounds as piles to anchor their building foundations, and gradually their fortunes improved. In 1428, they attacked and beat the most powerful city in the basin of Mexico—the Tepanec city of Azcapotzalco—and from that time they were the most powerful polity in the region. Tenochtitlan grew rapidly in both grandeur and size, ultimately reaching a population of an estimated 150,000–200,000 people and covering perhaps 20 square miles (50 square kilometers).

By the time of the Spaniards' arrival, the city was a metropolis of gleaming white houses and temples interspersed by canals and linked to the mainland by a series of causeways. In the center of the city was a sacred precinct, surrounded by a wall and containing the great temples of the city, a ball court, and a "skull-rack"—a structure that contained the skulls of tens of thousands of sacrificial victims skewered on wooden stakes. All buildings were dominated by a huge pyramid topped by twin temples: one was the house of the Aztec rain god, Tlaloc; the other, that of Huitzilopochtli, the war god and patron of the Aztec people.

Outside the precinct wall, but still at the heart of the city, were the palaces of the various Aztec emperors. Beyond these were the houses of the nobles and commoners laid out in a grid with canals serving as streets (several of the Spanish conquerors compared Tenochtitlan most favorably with Venice). The city was divided into quarters, and each quarter was divided into smaller units called *calpulli*. By all accounts, the city was very clean, orderly, and efficiently run. The great market of the Aztecs was in another city, Tlatelolco, immediately to the north of Tenochtitlan. There, some 60,000 people would pour into the market to exchange wares brought in from every corner of the empire.

After conquering the Aztecs, the Spaniards razed the city and began to build their own capital of New Spain—the city now called Mexico City. The Spaniards reduced most of the Aztec buildings to rubble, reusing many of the stones in their own constructions. Even so, the rubble reached in some parts to a height of about 10–13 feet (3–4 meters), which means that in many parts of Mexico City there are preserved remains of Tenochtitlan. Almost any deep excavation in the central part of the city will reveal such remains, and in 1968, excavations to extend Mexico City's subway system uncovered a perfectly preserved Aztec temple. It was kept as the centerpiece of the Pino Suárez subway station.

In 1978, a huge carved stone was found by electrical workers in central Mexico City. The stone was decorated with the relief of an Aztec moon goddess, Coyolxauhqui, sprawled dead and dismembered on the ground. In fact, the Coyolxauhqui stone was at the base of a stairway leading to the temple of Huitzilopochtli and recalled the Aztec myth telling how Huitzilopochtli killed his half-sister Coyolxauhqui, dismembered her, and threw her body down from Coatepec (Snake Hill). The Aztec Great Temple of Tenochtitlan, then, was the physical reconstruction of Coatepec, with the broken body of Coyolxauhqui at its base.

Subsequent excavation of the Great Temple has revealed the way in which the structure was enlarged over the years, each construction being larger and more elaborate in direct reflection of the growing fortune of the empire. The Great Temple was the ritual heart of the empire, and it was at the very center of Tenochtitlan.

Cuzco—Inca Capital

Cuzco, a name that derives from the mound of stones into which a mythic ancestor of the Incas

had been transformed, took shape as the greatest capital city of South America under the last three independent Incas, Pachacuti, Tupa Inca Yupanqui, and Huayana Capac, who ruled between about 1438 and the mid- to late 1520s. It was also one of the most elevated capital cities in history, situated at an altitude of 10,825 feet (3,300 meters) or roughly two miles high. According to a story recorded around 1550 by the Spanish historian Juan de Betanzos, at the beginning of his reign Pachacuti rebuilt the city according to a plan that he fashioned out of clay models.

The city, which was rectangular in form tapering toward the confluence of two streams, became the administrative and spiritual center of a fast growing empire. From Cuzco, the Incas divided their empire into four *suyus* (regions) that formed the *Tabua-ntin-suyu* (the four united parts). The quarters were the *Anti* sector, which covered the eastern Andean slopes and tropical lowlands; the *Colla*, which extended southeast to the Titicaca region and beyond; the *Cunti*, which stretched southwest to the coast; and the *Chincha*, which covered most of the territory north and west toward the equator. The quarters converged on Cuzco's Temple of the Sun in the Gold Enclosure, the most sacred precinct in the city. The area immediately surrounding Cuzco was a sacred landscape filled with 328 shrines that fanned out along conceptual lines called *ceques*. These shrines ranged from monumental buildings to natural features on the landscape such as crags and springs. Each had its associated stories that were part of the fabric of Inca sacred history.

As befit the capital of an empire ruled by descendants of the Sun, the Incas enforced the removal of both people and sacred objects to the capital. The transported people included skilled craftsmen and the sons of local lords. These latter were trained to fill lower positions in the Inca bureaucracy and were also expected to ensure the loyalty of the ethnic groups from which they came. Removal of a community's primary sacred object (*huaca*) to Cuzco was aimed at both coercing obedience from subject provincial peoples and incorporating their spiritual powers into the empire.

Chaco Canyon

The sight of the Great Houses of Chaco Canyon—vast multistory constructions containing scores, and in a few cases hundreds, of rooms built in a dry and inhospitable valley in northwestern New Mexico—is nothing short of extraordinary. These and other architectural edifices were built by the ancient Puebloan peoples who occupied the canyon and the surrounding area between about 950 and 1125 CE. The largest Great House, Pueblo Bonito, covers an area of 4.5 acres (1.8 hectares) and contains 700 rooms arranged in an irregular semicircle around a central plaza. The building increases in height from a single story by the plaza to five stories next to the outer wall. In the plaza itself were numerous kivas—underground chambers built for religious ceremonies—of various sizes, including two “great kivas” around 50 feet (15 meters) across.

One of the most intriguing questions about Chaco is why social organization and architectural technology should have reached such impressive heights in such an improbable place and how they were supported. It is clear that a

The extraordinary ruins of Pueblo Bonito in Chaco Canyon, viewed from the mesa to the northwest. (iStockPhoto.com)

huge and well-organized infrastructure was needed, for example, in transporting tens of thousands of large timber beams for the construction of floors and roofs over distances of 60 miles (100 kilometers) or more from the nearest forests. A key issue is the size of the resident population. It seems unthinkable that the scant food sources available could have supported a population that filled all the rooms of the Great Houses, and this, together with other factors such as the preponderance of kivas, invites the suggestion that the canyon was first and foremost a religious center, with a relatively modest number of permanent residents. If so, then it was likely controlled by an elite who exerted both ideological and political control. One suggestion is that pilgrims are likely to have converged here in considerable numbers at particular times and that these times would have been astronomically determined.

In recent years, convincing evidence has emerged that the houses, kivas, roads, stairways, and even middens around Chaco formed a carefully planned ritual landscape centered upon the Great Houses of the canyon itself. Within this scheme of things, it is perhaps not surprising that a number of buildings seem to have been deliberately oriented along one or the other of the cardinal directions or else display a strong degree of symmetry about their north-south

and/or east-west axes. Similar principles seem to have extended to the layout of buildings within the landscape, with several of the principal ones lying on an east-west axis and a north-south axis which cross in the valley. When these axes were first discovered, many scholars dismissed them as fortuitous rather than deliberate, but this changed with the subsequent discovery of the (Great) North Road, which connects with the north-south axis and runs due north from Chaco for more than 30 miles (50 kilometers).

The principles that defined the spatial layout of Chaco buildings and their landscape were apparently derived from a quadripartite cosmology, a perceived division of the world into four quarters around some central place. Such divisions have persisted as a characteristic feature of indigenous North American worldviews up to modern times.

Cahokia

The many huge earthworks or mounds that remain visible in the Mississippi and Ohio valleys form a conspicuous testimonial to the technical achievements of indigenous North Americans before the arrival of European settlers. Inevitably, a number of them have attracted interest in potential astronomical alignments, and it is scarcely surprising that this includes the great Mississippian site of Cahokia.

The Mississippian culture flourished from about 1000 to 1400 CE in the central Mississippi Valley, where the fertile floodplains were ideal for growing maize and other staple crops. Cahokia was not only the main economic and po-

litical focus of this culture but also the largest pre-Columbian town—worthy in fact of being called a city—north of Mexico. At the height of Cahokia's development it covered over 6 square miles (15 square kilometers) and had an estimated population of more than 20,000. The city itself was laid out on a grid that was roughly aligned along the four cardinal directions. At its heart was a ceremonial center containing over 100 earthworks, all serving as temple or house platforms or burial mounds. Most of this "mound center" is now preserved in Cahokia Mounds State Historic Site near East St. Louis.

The rectangular flat-topped earthwork known as Monks' Mound is at the center of the ceremonial grid. It is the largest earthen mound in the whole of the Americas, some 100 feet (30 meters) high and covering around 17 acres (7 hectares). But it was the discovery in the early 1960s of rings of postholes marking the sites of five timber circles to the west of Monks' Mound that triggered intense astronomical interest in the site. By analogy to Woodhenge—a set of concentric oval-shaped timber rings found near Stonehenge in England—the discoverers named them woodhenges, although it is dangerous to draw close similarities between superficially similar sites from completely different cultural contexts.

The five original woodhenges at Cahokia, identified by extrapolating from strings of postholes forming circular arcs running through excavated areas, appear to have had diameters ranging from 120 feet (37 meters) to 233 feet (71 meters). They were good approximations to true circles, with evenly spaced posts. Most remarkably, initial estimates of the numbers of posts in the five circles—24, 36, 48, 60, and 72—implied that numerology was vitally important and that strict design principles were operating. Four of the five posthole circles overlap, suggesting that they represent successive constructions fulfilling a particular purpose. Since this time, a number of other postholes and posthole structures have been discovered at Cahokia.

The original suggestion made in the 1960s was that the various circles of timber posts functioned as devices for observing the rising position of the sun at the solstices and equinoxes, perhaps for the purpose of regulating an agricul-

➤ MONKS' MOUND

(Alfred J. Andrea)

Monks' Mound, the largest earthen structure at Cahokia, contains an estimated 22 million cubic feet (623,000 cubic meters) of earth. It was at the center of the community, which included about 120 mounds over an area of 5 to 6 square miles (13–16 square kilometers).

—Alfred J. Andrea

tural or ceremonial calendar. However, this involved the totally arbitrary selection of data: for instance, three posts—indistinguishable in any other way from all the remaining posts in one of the circles—were identified as putative solar foresights as viewed from a central post. Other corroborating evidence presented at the time—for instance, relating to the orientation of the ramps used in setting each relevant timber post in its place—has proved totally fallacious, as have various further astronomical speculations.

An obvious question to have asked at the outset was why, if sunrise observation was the primary purpose, was a whole circle of posts needed? Indeed, circles of this size—unless supplemented by the use of distant horizon foresights—cannot define the relevant alignments at all precisely. It is possible that the circles had a cosmological function or meaning, but the publicity given to the unfounded astronomical speculations has undoubtedly hampered serious consideration of this issue.

Instead, Cahokia stands as an unfortunate example of bad practice: uncritical spotting of

alignments upon preconceived astronomical targets undertaken without due consideration of the broader interpretative context.

■ Introduction: The Human Environmental Imprint—Natural Resources

In many respects, the years 1000–1500 constituted, so far as the harvesting and use of natural resources across the globe were concerned, a period of expansion of the human imprint on the environment, but it was not one of revolution.

Essentially all of the important tools and techniques for farming, mining, and processing nature's bounty had been developed and spread beyond their regions of origin well before 1000 CE, and the world would not see significant developments in most of these technologies for several more centuries. Of course, there were exceptions to this general rule, especially in the case of improved water pumps that enabled several societies across Afro-Eurasia to dry out so-called wet wastelands, thereby reshaping the environment, often for agricultural purposes. Such reclamation had severe negative environmental consequences, but awareness of the damage done by drying out fragile sites such as these only became apparent in the late twentieth century. Pumps, along with other new hydraulic machinery, also allowed the extraction of minerals from deep within the earth, and this was especially true for China's coal and iron industries. To drive its iron production, which grew at a rapid rate during the Northern Song era (960–1126), the Chinese denuded vast stretches of northern forestland in their quest for charcoal. By around 1100, however, bituminous coke became the fuel of choice, which placed further pressure on coal mining and also added to air pollution. Some power sources were mercifully

far cleaner. Although the technology was essentially ancient, the use of water- and wind-driven devices, such as grinding mills and water wheels for irrigation, proliferated across Afro-Eurasia. The twelfth-century monastery of Clairvaux in Burgundy, France, for example, had a vast array of water-powered devices in its workshops. The brothers diverted half of the water from the Aube River onto the abbey's inner grounds. Once there the water did its duty, driving spinning wheels and a vast assortment of other machines, and as it flowed out of the monastery complex, it carried waste products, especially the vile remains of its tanning operation, to the river's main channel. One wonders what the Aube looked like downstream.

As with tools and techniques, most major foodstuffs had also spread widely within and across the still-isolated "world islands" of the Americas, Afro-Eurasia, and Australia well before the year 1000. Isotope evidence from human skeletons in southern Ontario, for example, indicates that maize had reached this region from central Mexico by about 650 CE, although it took centuries for it to achieve a place of prominence in the diet of local inhabitants. In like fashion, China had received most of its imported flora from central and western Eurasia, such as grapes, date palms, and melons, in the eras of the Han and Tang dynasties (202 BCE–918 CE). The one major exception was fast-growing drought-resistant Champa rice from Southeast Asia, which appeared in the Middle Kingdom during the early years of the Song dynasty (960–

1279). This rice, which allowed for double- and even triple-cropping, enabled China to expand rice cultivation far into its northern plains, and it was only during Song times that rice became central to the Chinese diet. Similarly, tropical Africa had, much earlier, received such important crops as bananas from across the Indian Ocean.

By and large, edible flora that developed exclusively in a single landmass (such as maize, potatoes, and peanuts in the Americas; wheat, barley, millet, and teff in Afro-Eurasia; and the small-leaved clematis in Australia) remained there and was isolated from the rest of the world until the great transoceanic voyages. The exchange that followed in the wake of these voyages, especially the so-called Columbian Exchange between the Americas and Afro-Eurasia, would have profound environmental, demographic, social, economic, and political repercussions but only after 1500. The only significant exception to the rule that unique plant foods remained isolated within their home landmasses before 1492 was the sweet potato, which somehow made its way from South America to Polynesia sometime probably between 300 and 700 CE.

Although cultivated flora and various tools for exploiting the environment remained fairly unchanged during this half millennium, the areas touched and altered by humans increased substantially, as did the intensity of that exploitation. The fourteenth-century double trauma of the first stages of the Little Ice Age and the Great Pandemic proved a setback to Europeans, who since around 900 CE had been intensely pushing out their physical boundaries while exploiting vigorously internal lands once thought to be marginal areas or wastelands. A retrenchment in Europe that lasted more than a century was now in order, although it did not stop sixteenth-century Western Europeans from expanding overseas and exploiting lands and peoples in the Americas. During the last quarter of the fourteenth century, the Chinese, despite having lost in the previous two centuries as much as 50 percent of their population due to invasions and disease, were moving in a major way into the southwestern frontier regions of Yunnan and Guizhou. Government soldiers, arriving as farmer-colonists, cleared and cultivated some 350,000 acres (140,000 hectares) of land by 1400.

Well before the fourteenth century, governments across Afro-Eurasia had encouraged colonization and cultivation of the land through a variety of means. European lords, especially those pushing out Latin Europe's eastern borders, offered special privileges and freedoms to the peasants who moved onto their lands. In China under the Song (and later the Ming) this encouragement took on a pedagogical form with the production of illustrated government-sponsored manuals that promoted best-practices farming techniques. One such manual printed in 1149 promised that anyone who planned carefully and acted accordingly would enjoy success as a farmer without having to rely on luck. A vast ocean away and several centuries later, all the "big-eared" nobles of the Inca empire, as well as the divine Inca himself, would on certain set days go into the fields and cultivate the land with a plow as an example to all of the worth of such labor. In the process, the face of the land across the world was being transformed.

Transformation is not necessarily a positive phenomenon. Although the reasons for their disappearance as identifiable cultures is uncertain, it is possible that the cliff and pueblo dwellers of the Four Corners (the so-called Anasazi) and the Hohokam of the Salt and Gila river drainage of present-day Phoenix, Arizona, abandoned their cities in part because they had exhausted the land.

—*Alfred J. Andrea*

Equatorial Agriculture in Africa

Cattle herding and banana cultivation provided the basis for socially complex and economically viable food systems in equatorial Africa during the period between about 1000 and 1500 CE. The mix of pastoral and farming communities also reflects the growing diversity of regional political strategies. Linguistic, ethnographic, and archaeological perspectives suggest that shifting food economies may also correlate with new political and social identities during the period.

The Great Lakes region comprises what is today southern Uganda, eastern Rwanda, and northwestern Tanzania, and scholars disagree about the historical origins of distinct cultural identities attached to contemporary herders and

➤ IRONCLAD POWER IN CENTRAL AFRICA

Iron technology in Central Africa not only played a key socioeconomic role but also functioned as a symbol of political authority in the region between the late tenth century and the mid-thirteenth century. Remarkable burials linked to the Early and Classic Kisalian Culture (late seventh through twelfth centuries) reveal the persistent symbols of high status in the form of ceremonial axes, iron bells, and anvils, the signature tool of the blacksmith.

The Upemba Depression, just south of the equator, is dominated by a fertile floodplain, where early technological achievements included complex iron and copper metallurgy and hydraulic systems that controlled water levels with dams and canoe channels. The largest copper deposits in the world are found to the southeast, and iron metallurgy dates back at least two millennia. Both copper and iron were smelted locally and traded long distances as ingots and currency. Metalworking techniques included wire drawing, hammering, and casting used to manufacture chains, pen-

dants, fishhooks, harpoons, spears, knives, hoes, and other goods.

Iron links religion, politics, and technology across the centuries and stretches from the Kisalian Culture to the Luba, a powerful kingdom after 1700. Miniature iron anvils are found in early burials as royal insignia on objects from hairpins to axes, and the anvil is the symbol of royal authority among the Luba even today. Blacksmiths and kings are similarly linked through their transformative powers, since oral traditions suggest that the first ruler was himself a smith. The use of iron symbolism to communicate ideas about sacred kingship and the underpinnings of political power may reflect the significance of iron in the agricultural and economic history of the region. The transformation of iron ore into malleable metal remains among the most powerful metaphors for strength and authority in Central African political and ritual realms.

—Candice Goucher

banana farmers there. The long process of Bantu expansion, a series of long-distance migration over millennia, involved both iron technology and mixed agriculture, eventually assimilating Cushitic and Sudanic linguistic groups. Intensive cattle herding appears after about 300 CE and as late as the eleventh and twelfth centuries in some areas. Long-standing trade and other connections brought into contact the varying economic lifestyles organized around livestock, cereal farming, fishing, and growing yams. Banana cultivation added to this mix by at least 1200 CE and subsequently spread to multiple groups. Based on historical linguistic and archaeological evidence, historian David Schoenbrun has argued that struggles for wealth and political authority may date from the period of the introduction of intensive banana cultivation.

Around the end of the first millennium or the beginning of the second, extensive iron metallurgy and clearing of land with iron hoes led to the diminishment of secondary forests south of the Kagera region (which is situated along the shore of Lake Victoria in present-day Tanzania). Specialized herding by Rutaran speakers eventu-

ally resulted in their movement into the drier and more open grasslands. Not only people but also practices shifted across the landscape of equatorial Africa. Whether or not societies emphasized cattle or bananas, they depended on religious specialists and political officials and their vocabularies of power. The family heads and chiefs, who controlled lands available for intensive cultivation, stood to gain in wealth and prestige as they distributed access to free lands.

Evidence of an increasingly important social hierarchy in the fourteenth and fifteenth centuries comes from the period's construction of large earthworks. These imply the highly centralized control over resources, including labor, at sites such as Ntusi, Bweyore, and Bigo, all in present-day Uganda. Burial sites have been excavated and reveal that elites and even their children were buried with extensive grave goods, such as decorated pottery, jewelry, ivory, glass beads, cowries, and metal currency shaped as crosses. Control over people and land, whether devoted to herding or farming, may have formed the foundations for great wealth and political authority within indigenous state formation.

Estimates of population are extremely difficult to make with any certainty during the pre-colonial period. Some scholars have claimed that the region's agriculture supported the most densely populated region in Africa. The banana thrived in the regions of generally good rainfall and fertile soils and, when cooked, provided a staple food for large numbers of people. Populations along the lakesides shifted during periods of occupation. Sharp increases in child burials can be interpreted as evidence of high child mortality or significant population increase, or both. The close association of populations with animal herds may have contributed to the spread of disease while also supporting exceptional levels of agricultural productivity.

Salt Production in China and West Africa

Salt, now common and inexpensive, was once neither. States became rich by controlling salt production and trade, and wars were often fought for it. Salt is a necessity rather than a luxury. Without enough salt, our bodies cannot retain or process water. In particular, grain-based diets are poor in salt, and agricultural communities have had to find a way to produce or acquire salt. An examination of salt production and trade in China and the West African savanna region provides us with insights into how agricultural societies in two very different world regions dealt with the problem of getting salt. Furthermore, these case studies give us insights into how the quest for salt influenced the cultures of each region.

East Asia was one of the first parts of the world to establish sedentary agriculture, and the area is also rich in salt. Brine springs and dry lake beds in the interior were sources of salt,

and communities along the seashore could extract sea salt by concentrating the brine and then boiling it. As early as at least the twelfth century BCE, Shang rulers taxed the production and distribution of salt, and by the time of the Qin empire (221–206 BCE), the government monopolized salt production. Salt remained under government control for centuries and during the Ming dynasty (1368–1644) provided more than half of the government's revenue.

Through a system known as *yin fa* (the syndicate system), families in salt-producing regions were required to produce an annual quota of salt. Licensed traders transported the salt to official government depots from where they then carried it to local markets. At each step, the salt was monitored by government bureaucrats.

Compared to East Asia, the inhabitants of West Africa were faced with much greater challenges in developing agriculture and gaining access to salt. However, by the first millennium CE, local farmers were overcoming poor soil and unpredictable rainfall. Soon the local population began to grow and create cities along the Niger River Valley. By the second millennium, large trading empires, such as Mali and Songhai, grew to dominate the savanna region. As elsewhere, these communities needed salt.

Unlike China, there were few local sources of salt in the Niger River Valley. The nearest significant sources lay deep in the Sahara desert, hundreds of miles to the north. The introduction of the dromedary, or single-hump Arabian camel, in the early centuries CE provided merchants, especially the Berbers of northwest Africa, with a superior means of reaching and transporting the salt. Caravans of several thousand camels, each carrying two large slabs of salt, became common, and indeed salt became just as important a part of the trans-Saharan trade system as the gold mined in the forests to the south. Mali and Songhai grew rich by controlling the flow of salt and gold into and out of their borders. In the early sixteenth century, Songhai seized the important Saharan salt mine of Taghaza in order to control salt production as well as its trade.

Salt in the savannas was generally acquired via trade, and this meant contact with foreign merchants. In particular, the trans-Saharan trade in salt put the ruling and merchant classes of the

➤ SALT MINES OF THE WESTERN SAHARA

Deep within some of the most arid regions of the Sahara desert lie a number of the most important salt mines of the premodern era. These deposits of salt are a legacy of the region's once temperate and well-watered past. Prior to 10,000 BCE, large lakes were present along the western and southern reaches of the Sahara, of which Lake Chad is the sole survivor.

When the Sahara began to rapidly dry up after 6000 BCE, the evaporation of the lakes created deposits of rock salt, some several meters thick. Populations in the agricultural regions of both North Africa and the savanna regions of West Africa gradually learned to exploit these salt deposits. The mid-fifth-century BCE Greek historian Herodotus mentions salt mining in the African desert, but it was the dromedary, introduced into North Africa early in the first millennium CE, that enabled entrepreneurs to reach and mine these remote deposits.

Major salt mines were established at Teghaza and Taoudeni, near the northwestern corner of modern Mali; Ijlil in northern Mauritania; Tichitt in southeastern Mauritania; and Awlil, on the coast near the northern border of modern Senegal. By 1500 CE, annual combined output was perhaps

Salt pits in Senegal. (Sarasta/Dreamstime)

more than 5,000 metric tons per year. The mining of salt was almost always carried out by slaves, in no small part because the conditions in the desert salt mines were so brutal. Upon visiting Teghaza in 1352, the traveler Ibn Battuta commented, “This is a village with nothing good about it.”

Given the value of the salt excavated from these mines, they were often the focus of political intrigue and military assault.

—Jonathan T. Reynolds

savannas in contact with their counterparts from North Africa. As a result, the trade in salt was a major conduit by which Islam was introduced to the region. By the fifteenth century, for example, many of the merchants and rulers of the savanna had converted to Islam. Notably, the founder of the empire of Songhai, Sonni Ali, was overthrown in part because he was not considered a devout Muslim.

In both China and West Africa, salt and society were deeply intertwined. In China, salt and the government became inseparable. Indeed, the Chinese character for salt shows a government bureaucrat standing next to a salt-boiling pan. Thus, control over the production and trade of salt in East Asia was a major factor in developing Chinese state authority. In West Africa, too, salt became a major source of state income through trade. Furthermore, because trade necessitated contact with the wider world, the salt trade in

West Africa became a major conduit by which a new religion was introduced into the region.

The Settling of the Kerala Backwaters

The southwestern coast of India, south of Mumbai, also known as the Malabar Coast, is a nar-

row strip lying between the Arabian Sea and the Western Ghats (Sahyadri Mountain Range). The Ghats, once covered by tropical rainforests, range in height from 2,000 to 8,000 feet (610 to 2440 meters) and in many places block the monsoon rains as they blow out of the Arabian Sea and cross the shore. As a result, heavy rains fall along the coast as the cloud banks rise and press into the mountains, seeking out the passes that will carry them across the Deccan Plateau and onward over the Indian subcontinent. These intense rains have shaped the unique environment of coastal western India. In the early modern age, numerous creeks, as large as rivers, rushed down the steep slopes of the Ghats to form an intricate pattern of mangrove swamps and estuaries feeding into lagoons separated from the sea by a chain of sandbars and islands.

In Kerala, the environment of the coastal lowlands differs from that of the northern regions of India's western coast. Here the land lies at sea level, almost perfectly flat and often flooded. What is perhaps even more intriguing about Kerala, however, is that its coastal landscape, known as the Backwaters, is mostly artificial. Like the polders of Holland, the Backwaters are the work of thousands of laborers toiling, over centuries, to harness rivers and win land from the sea. Deposits of marine shells are found at many inland villages in Kerala, and some of these places bear names that suggest that at one time they stood on the seashore. According to Hindu mythology, the divine culture-hero Purushurama raised the lowlands of Kerala from the sea in order to provide a paradise for the settlement of Brahmin priests and therefore atone for past sins. In Kerala, local lore attributes the formation of the lowlands to a "first king" of semi-divine origin.

The western coast of India was thinly populated in ancient times and difficult to farm due to heavy rainfall. Neolithic cultures flourished in this niche, however, some surviving intact well into the nineteenth century. Permanent agriculture carried out on a significant scale gained a foothold on the coast very late, probably in the ninth century CE, and thus farming developed in Kerala after the establishment of local economies based on fishing and commerce. As the first-century *Periplus of the Erythrean Sea* attests,

Kerala backwaters, India. (McKay Savage)

the coast supported several thriving ports, but these were trading posts where hunter-gatherers and herders brought jungle produce, mainly spices and rare woods, to the shore to trade. Eventually, foreign traders settled permanently on the Kerala coast, no doubt attracted by the area's cultural and political openness. Local rulers allowed Jewish, Syrian Christian, and Arab Muslim traders to set up towns and rule themselves according to their own customs.

The kings of Kerala were Hindu, albeit late converts to the Aryanized northern form of the religion. The absence of agrarian villages, however, precluded the rise of a Brahmin-dominated Hindu culture rooted in normative northern Indian notions of caste and dharma. The traditional Aryan pattern of Indian civilization, with its landholding priestly elite, required substantial surplus agricultural production, and in order to promote and anchor Hinduism, the rulers of Kerala had to create rich farmland, the famous Backwaters. The economic impetus for this effort probably was a combination of the need for more land to accommodate a growing population and the desire to profit by provisioning coastal trading enclaves. In any event, tribal communities that already had transitioned to slash-and-burn cultivation in the mountains settled down to permanent farming along the shores of coastal lagoons and built up more land by dredging up the bottoms of lagoons and building a

► THE WATERY, INVINCIBLE MAZE OF THE BACKWATERS

Divided into hundreds of islands by thousands of creeks, sloughs, estuaries, lagoons, and canals, the Backwaters were difficult to unite politically and impossible for outsiders to control. The raja of Cochin dominated the northern Backwaters, holding strategic forts guarding the main river channels along which spices were brought to the coast from the slopes of the Western Ghats. When the Portuguese arrived in Kerala, they allied themselves with the raja of Cochin against the Samudri Raja (Lord of the Sea, known to the Portuguese as the Zamorin) of Calicut, who threatened to invade the Backwaters from the north. Over time, as the Portuguese brought Cochin under their control, however, they found it impossible to impose their regulations very far beyond the limits of the port city and a few Christian villages on adjoining Vypeen Island. Edicts prohibiting the smuggling of pepper were especially ineffectual, since local people knew routes by which spices could be transported across the Backwaters, avoiding Portuguese checkpoints and dodging the Estado da India's monopoly. The Dutch, who took over Cochin in 1666, also tried to dominate the Backwaters but could not control Kerala any more successfully than the Portuguese. Pepper smuggling continued, and in the meantime the expanding state of Travancore, based in southern Kerala, extended its control over the interior hills and the southern Backwaters, eventually drawing the Dutch into a disastrous war that put an end to Holland's prolonged efforts to colonize the Indian mainland.

—James Hoover Frey

system of dikes. As new farmland was slowly developed, groups of Brahmin immigrants were invited to settle in the lowlands and were granted *agrabarams*, which gave them tithing rights over specific areas. These priestly lineages eventually coalesced to form the Nambudri caste, noted for its scrupulous adherence to rules governing ritual purity and pollution.

When the Portuguese arrived in 1498, the Kerala Coast had reached its present location, but the Backwaters were not fully developed. Rivers carrying heavy loads of silt into the Ara-

bian Sea had been striving with the ocean tides and monsoon storms for centuries, forming a chain of sandbars stretching hundreds of miles along the coast, miles out from the mainland, with semibrackish lagoons and marshes developing behind them. Port cities such as Cochin, the site of the first permanent Portuguese garrison in India, stood on one of these sandbar islands, an interface between the spice-producing tribal world of the mountains and the global trading system of the Indian Ocean.

The unusual ecology of the Backwaters has always intrigued foreign visitors to India. During the dry season, saltwater penetrated into the swamps from the sea, and during the monsoons freshwater backed up behind the coastal sandbar. Thus, the size and even the chemistry of the Backwaters were in perpetual flux. Sometimes, if the flood of freshwater broke through the bar and spilled into the ocean too quickly, the equilibrium of the environment could change radically.

Building narrow levees by hand—diving into the murky water to scoop up armfuls of mud with heavy iron hoes—low-caste laborers channeled runoff and drained small fields, subtly managing water flow, water levels, and soil chemistry to build up protected belts of new land, flooded with freshwater and suitable for intensive rice cultivation. The levees meanwhile were stabilized with thick plantations of trees. In a landscape won and maintained through such hard work, nothing was merely aesthetic. All of the trees served some useful purpose; vines were trained upon them for growing spices, and their branches and towering canopies provided shade for the small thatched houses constructed underneath them.

The people of the Backwaters lived abundantly in narrow spaces, adapting to their watery surroundings. As children they learned how to swim, and boats—ranging from small dugout canoes to cargo-carrying barges called *kettu-valams*—provided transportation. The narrow levees in turn shaped the social order: there were no nuclear villages, only strings of separate homesteads, each with its paddy fields, trees, and garden. The landscape of the Backwaters thus encouraged smallholders rather than the development of large estates. In Kerala, lineage, not

control of territory, remained the essential feature of the socioeconomic system.

Nomadic Life on the Central Eurasian Steppe

Pastoral nomadism was the dominant way of existence on the Central Eurasian steppe, a vast semiarid grassland that stretches from Mongolia to Hungary. Life centered on the so-called five snouts, the domesticated animals necessary to maintain nomads' well-being. The primary animal was the horse, essential for herding, hunting, and warfare and without which pastoral nomadism would have been impossible. As such, horses held an honored position as a symbol of life and status. Whereas wealth was based on the number of animals owned, the condition of one's horses was indicative of social standing. Sheep, the second snout, were necessary for their wool and meat. Goats, the third snout, supplemented the sheep, particularly where there was less pasture. The fourth snout consisted of cows or yaks, depending on altitude. Bactrian camels were the fifth snout. Although not one of the snouts, dogs were also important to the nomads for guarding the herds, particularly from wolves.

Felt from sheep's wool provided covering for the nomads' shelter known as a *yurt* in Turkish or *ger* in Mongolian, round tents with a wooden lattice framework that could be easily disassembled and loaded onto camels or placed on ox-

drawn wagons. Felt, along with camel and goat hair, was also used in the production of clothes, and leather was made from all of the animals' skins and used in a wide variety of applications.

Steppe nomads subsisted primarily on dairy products. Milk from all of the animals produced a variety of foods such as cheese, yogurt, and cheese curds. The Mongols also produced powdered milk. To use the concentrate, they would add water and tie the container to their saddles so that the movement of the horse could bring the mixture to a suitable consistency while traveling. A key item made from mare's milk was *kumiss* (*qumiz*), a fermented drink, normally of low alcohol content, that was consumed in large quantities in the summer due to the abundance of mare's milk after the foaling season. Although mutton dominated meals, meat from the other animals could be used. Due to their value, camels were rarely eaten.

Although animals supplied most of the materials needed to survive, complete self-sufficiency was nearly impossible. The nomads had a symbiotic relationship with their sedentary neighbors, typically states in China, oasis towns in Central Asia, and the Russian principalities. Nomads traded or raided these agrarian communities for goods they could not produce such as silk, grains, tea, and other luxuries. Although there were a few blacksmiths in the steppe, the nomads usually acquired metal weapons and tools from their neighbors.

It is often wrongly assumed that nomads simply wandered around in search of grass and water for their herds. In fact, they planned their migrations carefully so as not to exhaust pasturelands. In the summer, they moved to the highlands. In the winter, they migrated to the lowlands and into valleys. Of course, scarcity—generally brought about by drought or unusual population increases in either animals or people—could disrupt these patterns and lead to competition for pasture and eventual war between tribes.

Although large numbers of nomads congregated for war and tribal meetings, families typically lived miles from anyone else, driven by a need for sufficient pasture. A family could consist of a few yurts, usually one for each wife if the husband had more than one. Extended families

➤ MONGOL LIFE ON THE STEPPE

A mid-thirteenth-century Franciscan diplomat to the Mongols, William of Rubruck, reported back to the Latin West on various aspects of Mongol life, as the following two excerpts illustrate:

How to Make Kumiss

“And so, when they have collected a great quantity of milk, which is as sweet as cow’s milk when it is fresh, they pour it into a large skin or bag and they begin churning it with a specially made stick which is as big as a man’s head at its lower end, and hollowed out; and when they beat it quickly it begins to bubble like new wine and to turn sour and ferment, and they churn it until they can extract the butter. Then they taste it and when it is fairly pungent they drink it. As long as one is drinking, it bites the tongue like vinegar; when one stops, it leaves on the tongue the taste of milk of almonds and greatly delights the inner man; it even intoxicates those who have not a very good head. It also greatly provokes urine.”

The Head-dress of Mongol Women

“They also have a head-dress which they call *bocca*, which is made out of the bark of a tree or of any other fairly light material which they can find; it is large and circular and as big as two hands can span around, a cubit and more high and square at the top like the capital of a column. This *bocca* they cover with costly silk material, and it is hollow inside, and on the capital in the middle or on the side they put a rod of quills or slender canes, likewise a cubit and more in length; and they decorate this rod at the top with peacock feathers and throughout its length all round with little feathers from the mallard’s tail and also with precious stones. . . . So when several ladies ride together and are seen from a distance, they give the appearance of soldiers with helmets on their heads and raised lances . . .”

might stay in the same vicinity in order to share resources.

Both sexes shared the tasks involved in taking care of the animals, although there was division of labor under normal circumstances. Generally, men handled the animals unless they were hunting or away from the family for war or other reasons. Men also constructed the yurts and wagons, although this often became a task for the entire family. In addition, they churned the kumiss and manufactured saddles and other riding equipment as well as their own weapons. Women performed most of the household duties, such as cooking, making butter and other dairy products, dressing animal skins, and making felt. During migration periods, women also drove the carts and wagons. When the men hunted or were at war, the women cared for the animals. It was not unusual for either sex to do the traditional work of the other.

All nomads had some proficiency as archers with the compound recurved bow of the steppe, and both sexes possessed highly-developed equestrian skills. Children learned to ride at an early age, often before they walked. Children assisted in the care of the animals and were also responsible for procuring fuel for the fire. Wood was scarce on the steppe and was needed for the construction of yurts, bows, wagons, and other items, so it was not used as fuel. Instead, children gathered dried animal dung, which if properly dried burned with little odor.

Marriages were exogamous (outside of one’s immediate kin) and were often arranged while the intended husband and wife were young. It is not certain how extensive polygamy was among the nomads, but it did exist among the nobility. Furthermore, the nomads also practiced levirate marriages in which a widow is allowed to marry her brother-in-law if she agrees. Furthermore, a son could also marry the widows of his deceased father, excluding his own mother, thus ensuring their economic security.

Due to the often precarious nature of a life that required men and women to frequently perform the same duties to ensure the family survival, pastoral nomads tended to have a strong egalitarian streak in their institutions. There was social and political differentiation but much less so than in the patriarchal agrarian societies that

bordered the steppe. Egalitarianism was most apparent in gender relations, responsibilities, and social status. Even in the upper levels of society, women could play an overt role in politics, such as the regency of Töregene, a wife of Ögödei (r. 1230–1240), the second Mongol Khan, who ruled the empire as regent from 1240 to 1246. Indeed, women frequently served as regents at regional levels for the domains of the Mongol princes. Mothers and wives also served as advisors at all levels of society. On several occasions Chinggis Khan (1162–1227) turned to the advice of his mother Ho'elun as well as his wife Börte. Before setting forth against the Khwarazmian empire in 1219, he heeded to the suggestion of another wife, Yesui, and selected a successor. Women were still subordinate to men, but their nomadic lifestyle allowed for a wide latitude of flexibility.

Egalitarian behavior also manifested in the leadership of tribal confederations. There is a widely held but completely inaccurate perception that various leaders of nomadic confederations and empires, from Attila the Hun to Chinggis Khan, exercised absolute control and domination over their people. Tribal leaders were expected to lead effectively and to provide for their people. Those who failed to do so might be ousted from power or find themselves deserted by their followers, especially the great warriors, as they left the tribe to seek a more capable leader.

While not a democratic process, the selection of a khan, or leader, did not necessarily follow any rule of dynastic succession. Candidates were selected from a pool of qualified individuals from the tribe's aristocratic families, with ideally the most suitable selected to rule. It was possible to develop a line of succession for the purpose of nomination, but no nominee was guaranteed success. The previous ruler's nomination was considered a suggestion rather than a decision. Moreover, leadership could move laterally to a brother or a cousin rather than to the ruler's son.

When it came to inheritance the eldest son was not the primary recipient. All sons, and sometimes the daughters, received a share. Indeed, the youngest son received the father's home and pasturelands. Because of their age, elder sons were expected to have established families and

pasturelands of their own and thus were not in need of as much assistance as the youngest son.

This system of inheritance was applied by strong rulers who could impose their dynastic succession decision by dividing up and allocating imperial territories to their heirs. While not necessarily the best decision, it sometimes prevented heirs from engaging in internecine warfare in the short term, but it eroded the stability of the state over time. Appanages (lands given to heirs, especially younger sons) gained through this form of inheritance became smaller and smaller as each son subdivided his territory to his heirs. As territories decreased in size and available resources, conflict arose. Furthermore, because lines of succession were somewhat amorphous, there were more candidates for the throne, and if they were not handled properly, warfare erupted.

Nonetheless, nomadism remained the primary form of economy and society in the Central Eurasian steppe until the nineteenth century. During this period, Chinese and Russian immigration began to forever change the steppe. Although pastoral nomadism endured, it became increasingly marginal.

Europe's Agricultural Revolution

Between 1000 and 1300, Europe experienced a revolution in agriculture due to a milder, drier climate that lengthened growing seasons and improvements in tillage methods, soil management, and crop rotation that had been under way for several centuries before the year 1000. The consequent increase in food production and better nutrition led, in turn, to a substantial growth in population that had begun as early as the seventh century but took off dramatically between about 950 and 1050, depending on the

► CLEARING AND SETTLING MARGINAL LANDS

Beginning in the Early Middle Ages, agricultural laborers undertook a dramatic clearance of marginal land across Europe in order to expand arable ground to feed a burgeoning population. The clearance of woodland in England provides an excellent example of this activity. By 1086, the time of the Domesday survey, or census, of the kingdom, approximately 15 percent of England was wooded. From about 1086 through 1286 the island's population grew rapidly, causing a pressing and urgent need for agricultural land. The response to this demand led to a land-clearance effort that brought fen, waste, forest, and all other varieties of land under the plow. Farmers expanded their holdings in a piecemeal fashion, often clearing small patches of land, called *assarts*, in and along the edges of forests or wastelands. These *assarts* slowly encroached upon the woodlands. In Chilterns and Sussex Weald nearly 450,000 acres (183,000 hectares) of woodland were cleared in approximately 260 years. Extensive clearances occurred in the wooded areas of Warwickshire, Worcestershire, Surrey, Berkshire, Northampton, Derbyshire, Staffordshire, Yorkshire, Somerset, Dorset, and Suffolk. Finally, by 1350 the area of England that remained wooded had shrunk to 10 percent. One-third of the wooded land had been cleared.

region. The result was that Europe's human numbers probably at least doubled, and maybe even tripled, between 1000 and 1300 despite a high infant mortality rate and a sterility rate among adults that might have been as high as 33 percent.

The first important innovation was a new plow suitable for use in the rich soils of northern Europe. As the Romans moved north of the Alps, they had found that the light, or scratch, plow, which worked well in the light, dry soils of their Mediterranean homeland, could not stand up to the heavier soils north of the Alps, which needed to be turned and often drained. By the end of the sixth century, the heavy, or wheeled, plow appeared in Western Europe to handle this heavy soil.

The scratch plow, which remained in use around the Mediterranean until at least the late eighteenth century, consisted of a light wooden frame with one V-shaped, or triangular, plow-share (cutting blade) that an ox or a man could pull. Inasmuch as the plow barely disturbed the soil, the farmer often had to work the soil twice, cross-plowing for maximum effect. The heavy plow was much larger with wheels and required several oxen to pull it. Most important, the heavy plow's more complicated share and moldboard (the curved plate that turns and breaks up the soil) could completely turn the soil, leaving a furrow and exposed earth. Turning the earth in this manner helped dry out the heavy, damp soil and eliminated the need to cross-plow, reducing labor.

The new plow required more traction, and two subsequent inventions appeared that enabled farmers to make full use of it. The first was the padded horse collar, which originated in China no later than the first century BCE and reached Western Europe by the mid- to late ninth century, and the second was the horseshoe, which reached Europe by the late ninth or early tenth century. As with the horse collar, the horseshoe probably developed far to the east, either in China or Mongolia, around the first century BCE and likely traveled west across the steppes with various nomadic peoples out of Inner Asia.

Centuries earlier, farmers had mastered harnessing oxen with a yoke that rested on the animals' shoulders. Thus, harnessed oxen initially pulled the new plows. Horses were stronger, with more stamina, but ancient and early medieval horse harnesses in the West ran around the animal's neck, which meant that the weight of any load exerted pressure directly on the windpipe, choking the animal and diminishing the work it

could do. The padded collar went on over the horse's head but rested on its shoulders, keeping its windpipe open. With the introduction of the iron horseshoe, which saved the horse's hooves in damp earth, the horse was a valuable traction animal in almost any soil type.

Another major innovation of Europe's so-called Early Middle Ages (ca. 500–1000) was the three-field rotation. Before this, peasants had rotated crops between two fields, using one field for a crop each year and allowing the other to lie fallow and rejuvenate. In this system, farmers used only half their land at a given time. By the late eighth century, cultivators in some areas divided their land into three parts, two of which they farmed in a given year and one of which was left fallow, putting two-thirds of the land into use at a given time and greatly increasing the output and flexibility of the medieval manor or farm.

Much of northern Europe was ideal for the three-field rotation, but peasants soon found that some land was not fertile enough to support the demands of the rotation. Local tradition, established landholding patterns, or a conservative approach to farming also influenced some villages to continue using a two-field rotation, while their neighbors changed to the new system. Communities using two- and three-field rotations continued to exist side-by-side in Europe into the Early Modern Period (ca. 1500–1750).

Despite optimum weather patterns and improved agrarian practices, by about 1300 Europe's greatly expanded population was outstripping its ability to produce food, leaving it vulnerable for when the climate changed and other natural disasters ensued, as happened in the fourteenth century.

Scandinavia—Making a Living in Europe's Far North

In Scandinavia, the Viking era was followed by a period of political consolidation, and fixed borders came into place in 1101. The demographic picture is uncertain, as censuses were not undertaken until the seventeenth century, but between 1000 and 1300, a period of temperate climate, Scandinavia experienced a population growth as more marginal land was cultivated, especially through dairy farming. This also led to a stronger stratification of society. Fewer peasants owned their own land, and by 1300 the Crown, the Church, and the nobility owned a larger share.

Wheat was the most important crop in Denmark and southern Sweden, while barley, oats, and rye were more common farther north, where hunting and gathering also supplemented the diet. While people in the southern regions of Sweden and in Denmark lived in villages, the single homestead was most prominent elsewhere in Scandinavia. Fisheries were also important, and while the herring in the Baltic was unpredictable, the seasonal cod fisheries in the North Atlantic proved more certain. Together with timber from Norwegian and Swedish forests, fisheries also provided lucrative cash income from the twelfth century onward for those enjoying trade privileges.

The Black Death first reached Norway by a ship arriving in Bergen from England in the summer of 1349, and the disease had affected most of the country by the end of the year. In 1350 the plague reached Denmark and Sweden. The general mortality rate in Europe due to the plague was about 45–50 percent, but it is estimated that up to 65 percent of the population perished in parts of Scandinavia. The plague became a recurrent epidemic throughout the remainder of the so-called Middle Ages, and population growth did not pick up until the sixteenth century.

In addition to the general traumatic effect of the disease, another consequence was more land available for commoners. Protein and fat became

➤ A TALE OF A PROSPEROUS FISHING COMMUNITY

In the winter of 1431–1432, the Venetian merchant Pietro Querini capsized off the coast of Lofoten in northern Norway, and he and 11 of his crew of 68 were rescued by the islanders from Røst. Querini later wrote an account of his three-month-long stay that offers a unique insight into the lives of ordinary people in these parts, who in Querini's tale stood out as noble primitives in contrast to the decadence of his native Italy.

Querini estimated that 120 people inhabited around 1.4 square miles (3.6 square kilometers), a relatively low density that allowed for rich fishing in the surrounding waters. As with the population in most of northern Norway, the people of Røst depended on trading surplus fish for almost all other supplies and staples they needed, most importantly grain, as farming was difficult in the harsh climate except for keeping the occasional cow. But according to Querini, the fisheries (mostly halibut and cod, the latter the basis for the famous dry fish export) were so abundant that the islanders enjoyed a rich and varied diet. Official documents also reveal that during the late Middle Ages, a fisherman from places like Røst paid three times as much tax as the average peasant in Norway's richest agrarian communities.

—Frode Lindgjerdet

common foodstuffs for the greatly reduced population, as livestock was not affected by the plague. However, the Church and the aristocracy experienced an economic crisis as land-tenure rents and land prices plummeted.

Agricultural Technology in Mesoamerica

In the period immediately prior to the arrival of the Europeans, the native peoples of Mesoamerica

pursued three major types of agricultural technology. One had to do with the control of water to agricultural lands, including irrigation; the second involved soil preparation; and the third involved planting and tillage practices.

Mesoamericans adopted irrigation methods at nearly the same time that agriculture began in Mexico. Through the use of ditches and canals, two types of water were channeled for agriculture: water from springs and seasonal or continual flows from rivers and streams. In the central highlands there is also evidence of the construction of dams and irrigation canals to distribute water to fields. In some low-lying areas the problem was excessive water rather than too little. In these areas native peoples, especially the Maya of the Yucatan lowlands, cut drainage canals to move excess water from fields. In the Valley of Mexico, the Nahuatl people used the *chinampa*, or floating garden, to establish crop lands in marshy areas.

The second technology involved the preservation and enrichment of soils. Since Mesoamerica lies within the tropics, the effect of sun and rain on soils can be disastrous, with soils losing fertility and friability in just a few seasons. Consequently, lands were tilled for as many as three years and then allowed to lie fallow for a period of from three to seven years. The accumulated brush was then burned, allowing the nutrients to partially return to the soil and also sterilizing the soil from weed seeds. Croplands were also enriched by the muck and aquatic plants brought up from adjoining canals. Lastly, human feces and other waste products were added to the soils.

When it came to tillage and planting technologies, the native peoples of Mesoamerica lacked beasts of burden to harness to plows. Consequently, seeds were planted normally not in furrows but in hills. A digging stick was used to create a hole into which the seed was placed. The natives also developed a system of plant symbiosis known popularly as the Three Sisters, which entailed the planting of maize (corn), beans, and squash in the same hill. The maize provided a support for the climbing beans. Inasmuch as maize rapidly depletes the soil of nitrogen, beans, being a nitrogen-fixing legume, replenish that nutrient in the soil. On their part, squash plants provide broad leaves to protect

CHINAMPA

The *chinampa*, or “floating garden,” is traditionally long and narrow, some 13–23 feet by 130–200 feet (4–7 meters by 40–60 meters). In the Valley of Mexico, marshy land was reclaimed by creating a matlike surface of aquatic plants, reeds, or other organic material. This was fixed to the bottom of the lake using poles. Then willow trees were planted in the corners and along the sides for stability and to prevent erosion. Over time, compost and human, animal, and vegetative waste were spread on the surface along with muck dredged from the lake bottom until a fertile and stable surface was created. Eventually the plot of new open land, rising several feet above the lake surface, became stable enough to plant crops. The *chinampa* provided continual moisture to the roots of crops planted on it, and the trees and surrounding water created a microclimate that was less susceptible to fluctuation. Scholars studying present-day land distribution in the Valley of Mexico have discovered that many plots are based on pre-Columbian *chinampas*.

the soil from the percussive effects of tropical rain as well as to shade the soil so that nutrients are not leached due to excessive sun. The structure of the leaves and vines of the squash also tends to channel the rainwater back to the base of the plant. Furthermore, beans and maize complement one another in the diet, providing all the essential amino acids, or protein. Squash provided a rich variety of vitamins and minerals to the diet, which was supplemented by equally nutritious chilies, tomatoes, and other fruits, such as avocados and guava. These fruits were cultivated in household gardens normally adjacent to family compounds. In addition to foodstuffs, native peoples also cultivated cotton and maguey for their fibers. Maguey also provided sap that was fermented into the drink known as pulque.

Harnessing Desert Rivers—The Hohokam

Around the time of Christ, a Southwest culture known for the construction of massive irrigation works, later called the Hohokam (“those who have gone”) by the Akimel O’odham people (“River People,” also known as the Pimas), emerged along the middle Gila River in the Sonoran Desert region of southern Arizona. The civilization arose, according to most scholars, in four distinct stages: Pioneer (1–600 CE), Colonial (600–900), Sedentary (900–1100), and Classic (1100–1400). Some scholars in the past postulated that Hohokam culture did not truly arise until the migration of peoples from Mexico, yet this theory has all but been abandoned today.

In order to survive in the harsh desert environment, the Hohokam built an elaborate

THE EXTENT OF HOHOKAM CANALS

Ruins of Pueblo Grande, a major twelfth-century Hohokam village along a network of canals, in present-day Phoenix, Arizona. (Alfred J. Andrea)

With very crude tools the Hohokam built a series of canals spanning the Salt and Gila rivers. Their irrigation canals are considered to be the most extensive and sophisticated hydro-engineering system devised by North American Indians, only surpassed in size and scope by the hydraulic societies found in Peru. Many archaeologists surmise that they built somewhere between 125 and 315 miles (200 and 510 kilometers) of canals in the vicinity of Phoenix. Many of the contemporary Salt River Project canals located in the Phoenix area are actually refurbished canals from the days of the Hohokam. So far archaeologists have found that the Hohokam dug ditches measuring as much as 10 feet (3 meters) wide and 15 feet (4.5 meters) deep. Moreover, it is estimated that at their height their canals irrigated from 65,000 to 250,000 acres (25,000 to 100,000 hectares) in the Salt River valley alone. It was on the basis of this canal system that they built a whole series of irrigation communities that sustained Hohokam society and culture.

—John S. Leiby

network of canals encompassing hundreds of miles. Archaeologists have surveyed more than 100 miles (160 kilometers) of such irrigation canals in the Florence area and even more in the Phoenix area (see the sidebar). While the Hohokam relied heavily on the canals they dug, they

also channeled water via hillside terraces known as *trincheras* to retain as much rain drain-off as possible.

The Hohokam harvested and cultivated a host of wild, semidomesticated, and domesticated crops. As with nearly all North American Indians, they grew maize (corn). Some of the other plants they harvested included little barley, chenopods, amaranth, panic grass, devil's claw, and agave. Some scholars have asserted that Hohokam were major cultivators of agave, as signs of this production have been located near the northern Tucson Basin where irrigation canals were not needed due to sufficient rainfall. Because of recurrent floods, the Hohokam had to continually rebuild or abandon many of their canals. The largest such flood occurred in 899 and made irrigation farming untenable for a few years thereafter.

Despite these obstacles, Hohokam culture persevered and even expanded between 700 and 1150 CE. In addition to their canals, they are known for their distinct pottery (red on buff) and their sophisticated ball courts (some 200 have been unearthed by archaeologists). After 1100 Hohokam culture began to decline, probably in part because of the competition of their various communities for the scarce resources of the Arizona desert.

Andean Agriculture under the Incas

Access to the varied foods of highly contrasting ecological zones has always been of prime importance for Andean peoples. In fact, the vertical world of the Andes almost obligates access to these different environments and their produce. Thus, protein in the form of subtropical beans

➤ ALTITUDE ADJUSTMENTS

Agrarian and pastoral activities in the Andean world were (and are) very much determined by altitude. The lower altitude valleys, known as the yunca zone, extend from around 6,562 feet down to 2,625 feet (2,200 to 800 meters), below which are the coastal plain and Pacific coastline to the west and the tropical lowlands to the east. The yunca zone was warm enough to cultivate delicate crops such as peppers. Around 10,827 feet (3,300 meters), nightly frost can damage crops. Consequently, maize cultivation was not generally attempted above this height, except where there were favorable microclimates. Efforts to develop

arable land transformed steep mountainside gradients into stepped, or terraced, fields (known as Andenes) with irrigation canals channeling running water. Frost-resistant food crops, such as potatoes, were grown at altitudes up to and just above 13,123 feet (4,000 meters). Above this altitude, the puna grasslands that extend up to glacial zones were ideal for the pasture grazing of camelids. The domesticated alpaca and llama and the wild guanaco and vicuña provided humans with transportation, fuel, clothing, and food.

—Paul R. Steele and Catherine J. Allen

➤ ANDEAN MOUNTAIN SHRINES

Probably stretching back to well before Incan times, mountain shrines outside a number of remote Andean villages link mountains, ancestor worship, ritual pilgrimage, and the sea into a spiritual matrix that is the ultimate source of water and fertility. The landscape was seen as animated in the sense that unusual or prominent features were perceived as having a supernatural quality. Local communities often regarded themselves as the descendents of mountain deities. Consequently, mountain peaks—and especially volcanoes—occupied a prominent place in their cosmic beliefs and communal rituals. Mountains and mountain gods were seen as the controllers of rain, and their summits often became important foci of ceremonial activities. These metaphysical convictions had a foundation in the physical world in that prominent mountains have a strong effect on local meteorological phenomena.

Numerous shrines have been discovered on hills and mountain peaks in Peru, Bolivia, Chile, and Argentina. Seashells and river stones were commonly offered to deities for water, but more macabre offerings have also been uncovered: human (including child) sacrifices. Spanish chroniclers record that elaborate pilgrimages were involved in reaching these sacred places. But the intensity

of conviction that motivated the expeditions still defies the imagination. Offerings have been found on mountain peaks as high as 20,000 feet (6,000 meters).

There is every reason to believe that some of the mountain pilgrimages were tied to specific calendrical rituals and that they were astronomically timed. Broadly similar sets of beliefs and practices in central Mexico provide more concrete evidence of calendrical and astronomical associations. However, the specific associations that regulated the Andean rituals remain largely unknown.

and dried fish from the Pacific Ocean was supplemented by high-altitude grains and tubers.

Quinoa is an ancient and important protein-rich grain in the Andes that requires little warmth. Quechua and Aymara lexicographers translated wild quinoa as the word *Ayar*. In the Cuzco area, the most influential pre-Inca inhabitants were the Ayarmaca, a name made up of two food plants, *ayar* (quinoa) and *maca*. Maca is an edible root found on the *puna* (high plains) of central Peru and formerly found throughout the high Andean plateau. According to popular myth, the cultivation of maca represents an ancient agricultural tradition in the *puna*, predating the domestication of the potato. Maca is thought to have magical or hallucinogenic properties, and like quinoa, maca is also believed to have special associations with fertility. Thus, the Ayarmaca derived their name from two plants that had magical properties and were adapted to the high altitudes. Later, the Incas adopted the name *ayar* for their own ancestors. This connected them to their most important predecessors, further justifying Inca rule.

The potato—a staple of life throughout much of the Incan-dominated Andes—was domesticated between 5000 and 2000 BCE on a high plateau close to Lake Titicaca, which lies on the border between modern Peru and Bolivia. The high-altitude climate lent itself to long-term storage of potatoes through a process of freeze-drying. During the dry months of May, June, and July, farmers spread potatoes on the ground to let them alternately freeze and thaw, squeezing them during the day to promote the process. The result was a dehydrated potato that could be stored for several years and reconstituted by soaking in water.

Unlike these hardy tubers, American corn, or maize, was more susceptible to frost and required more ingenious techniques of irrigation on terraced slopes to sustain its cultivation at high altitudes. Despite the difficulty of raising this crop, maize production was vigorously promoted by the Inca state and regarded as its most sacred food because it was intimately linked to the cult of the Sun, the divine ancestor of all Incas. Dramatically increased production of maize under the Incas during the fifteenth and early sixteenth centuries was used to pay workers on

state projects in the form of fermented maize beer known as *chicha*. Maize beer was also the principal beverage for ceremonial practices and enjoyed a higher status than other foods.

Despite its statewide cultivation under the Incas, maize was a marginal staple crop compared to the potato. The tuber actually produces more high-quality protein from less land than maize, wheat, or rice.

Agricultural Life on the Pacific Islands—Environment and Population

Before the coming of Europeans, Oceania's major food crops were taro, yams, and bananas, all of Southeast Asian origin, and sweet potatoes, of South American origin. Domesticated animals included pigs, chickens, and dogs, all brought from Southeast Asia. Throughout this vast region, the cultivation of crops was done without draft animals. From weeding to harvesting, everything was done by hand, and large amounts of land lay fallow at any given time. However, because most of Oceania lies within the tropics (with the exception of New Zealand), farming was not confined to any season and could be done year-round. Moreover, clever farming techniques were adapted to particular environments and used throughout Melanesia, Micronesia, and Polynesia.

In Melanesia, especially in New Guinea, farming allowed the human population to reach and then exceed the carrying capacity of the land. Revenge warfare, so associated with highland New Guinea, may have operated as a kind of population control. In New Guinea only a tiny fraction of food came from wild resources as increasingly more of the land was transformed for

farming. Throughout the highlands sweet potatoes became the staple food, often encompassing more than 90 percent of the diet. To protect the sweet potatoes from pigs and to control the amount of water, the potatoes were often planted in ditches. As in the rest of Oceania, the hard work of clearing the land for farming and the dangerous work of guarding the fields from enemy warriors fell to men, while women were more often responsible for mulching, weeding, and harvesting. Magical practices, usually performed by men, were given much credit for the amount and quality of a harvest.

In Micronesia, where most of the land was comprised of coral atolls only a few feet above sea level, the main problem facing farmers was their inability to escape the salt water near the shore and that which percolated up through the land farther from the shore. Coconut palms provided much of the food and resources in Micronesia because of the plant's resistance to salt water. Because of salinity problems and the limited amount of land, Micronesians remained more dependent on fishing than did other groups in the Pacific.

Polynesia, which is comprised largely of mountainous volcanic islands, was home to a greater variety of crops. Chiefs assigned land to farmers in pie-shaped wedges that extended from the coast up to the mountains so that every family would have access to all of the ecological niches created by differences in elevation. Some plants, such as yams, grew better at lower elevations, and some, such as taro, grew better at higher elevations. The most important crops were sweet potatoes, yams, taro, and bananas, but also important were breadfruit, mountain apple, pandanus, kava, and many fruits. The bark of the paper mulberry tree was pounded into fiber for clothing. In Hawaii, irrigation systems were constructed to grow taro. The domesticated animals present throughout Polynesia were pigs, chickens, and dogs. In Hawaii the construction of coastline fish ponds meant that fish could be harvested much like crops.

THE SWEET POTATO'S VOYAGE ACROSS THE PACIFIC

With one exception, every domesticated plant and animal in Oceania originated in Southeast Asia and in most cases was intentionally brought via canoe onto the islands of the Pacific by the first human colonists. The one exception was the sweet potato, which originated in South America. Scientists are confident that sweet potatoes were domesticated in South America because it is only there that wild species still exist. The mystery is how sweet potatoes made the voyage from South America across the Pacific to Melanesia long before Europeans arrived on the scene.

Many theories have been developed to solve the mystery of the sweet potato's spread. Until genetic evidence confirmed an Asian origin for the peoples of the Pacific, it was even hypothesized that Oceania was settled by natives of South America who brought sweet potatoes with them. What probably happened is that Polynesians, already accomplished seafarers, made contact with people in South America and brought sweet potatoes back to Polynesia. Supporting evidence for this theory comes from linguistics. For example, the Quechua-speaking natives of Peru call the sweet potato *kumar*, while the Austronesian-speaking natives of Easter Island call it *kumara*.

Harvesting the Seas in Oceania

Marine resources were a vital component of economic and cultural systems throughout Oceania. People used the faunal resources of the Pacific Ocean as an important source of protein in their diet and as a source of raw material for various technological and decorative artifacts. Oceania is not a homogeneous geographical region, especially in terms of climate and resource availability. For example, there is a tendency for the richness, or number of different species in an ecosystem, of both terrestrial and marine species to decrease from west to east across the Pacific. As a result, people who moved throughout

Oceania were constantly adapting local marine resources to meet their needs.

The Pacific Ocean provided one of the few plentiful protein sources available for many of the peoples and cultures in Oceania. The region was generally poor in wild terrestrial fauna. Wild animals were generally limited to creatures such as birds, bats, seals, and sea lions that could swim or fly to various islands. Seals and sea lions spend most of their lives in the water, but their breeding grounds, usually along rocky shores, provide a prime source of protein for opportunistic hunters. Yet these resources were fairly rare, as most islands in the Pacific Ocean did not support very large populations of marine mammals. One major exception to this pattern of islands lacking terrestrial protein sources was Aotearoa (New Zealand), once home to a genus of giant flightless birds known as moa (which were hunted into extinction) as well as large breeding seal and sea lion populations.

It has been suggested that Oceania should be regarded as a sea of islands in which the ocean is an important component of daily life rather than a boundary, as it often appears to people living on continents. This was especially true for food procurement, where marine resources often played an equal or greater role in the Oceanic diet when compared with food resources gained through farming, hunting, or gathering wild plants. For many people throughout Oceania, in-shore reefs, teeming with fish and shellfish that could be easily harvested, provided a veritable feast. In contrast, the open ocean provided rarer but perhaps more highly prized fish species, such as tuna and mahimahi. In addition to fish and shellfish, various marine invertebrates, such as octopus and sea urchin, were important foods. Finally, various sea turtles and their eggs served to round out the high-protein offerings of the Pacific Ocean.

Yet marine resources were not simply a source of protein for people in Oceania. They also played important technological and symbolic roles in Oceanic cultures. Shells were used throughout the region to manufacture various kinds of fishhooks and lures. In addition, people in Oceania used decorative shell objects, such as rings or beads, in important ritual exchange

► MAORI IMPACT ON MARINE MAMMALS IN AOTEAROA

The Polynesian people who first colonized the islands of Aotearoa, now known as New Zealand, encountered a unique environment in the region. Aotearoa was larger and colder than any of the other island groups in Polynesia, but the Maori adapted quickly to this unfamiliar environment and flourished. Perhaps the most dramatic impact of the Maori on marine resources in Aotearoa was on the large New Zealand fur seal and sea lion populations. Fur seals were especially vulnerable to Maori hunting practices, and the animals' breeding range shrank rapidly. Among the many reasons for population decline were the aggressive hunting strategies employed by the Maori in the first centuries of colonization in Aotearoa and the conservative breeding practices of fur seals, which would only produce one pup per year. Within a few centuries of the initial arrival of Maori in New Zealand, seal and sea lion populations had migrated south, disappearing from North Island completely by 1600 CE.

—James L. Flexner

networks stretching hundreds of kilometers. In island groups where stone was not readily available, people used marine shell as a raw material for adze technology, such as Terebra-shell artifacts excavated from archaeological sites in the Mussau Islands northeast of Papua New Guinea.

Fish could also play an important ideological role in Oceanic culture. Hawaiian people enjoyed a complex toolkit of various fishhooks and lures, which developed from a more general Polynesian fishing technology. Hawaiians also developed the only true aquaculture in the region. All of the major Hawaiian islands have fishponds (*loko i'a* in Hawaiian), which were built to increase the concentration of fish, specifically milkfish (*Chanos chanos*, *awa* in Hawaiian) and mullet (*Mugil cephalis*, *'ama'ama* in Hawaiian). The earliest fishponds may date to the thirteenth century CE. These fishponds were important

symbols of Hawaiian chiefly power and were an integral part of the Hawaiian political economy.

■ Introduction: Population Trends

Of all of the subfields of historical research, demographic analysis is the most difficult and least exact, especially the farther back into the past one goes. As the following entries illustrate, recorded data are sparse at best for all areas of the inhabited world during that half millennium, despite the attempts of some governments, most notably imperial China, various Muslim states, Italian city-states, and the English Church, to keep records of such important pieces of information as taxable households and births, baptisms, and deaths. Beyond that, what records we do have are inevitably flawed and fragmentary. Moreover, all other forms of evidence, such as the archaeological remains of settlements, are ambiguous, open to wide differences in interpretation, and equally incomplete if not more so. Complicating the process further are the occasional demographic controversies that are colored by political or social perspectives. The most notable example is the debate that rages between the proponents of

high and low estimates of the native populations of the Americas, and especially of Mesoamerica and the Caribbean, on the eve of European contact.

Despite these impediments, there are some things that can be said in general about the population of the world between 1000 and 1500. It is clear that for most of the world, population figures were on the rise from 1000 to roughly the middle of the fourteenth century, and then there was a sharp drop-off due in large part to environmental changes and, so far as Eurasia and northern Africa were concerned, the Great Eurasian Pandemic that broke out toward mid-century and reoccurred in waves for several centuries thereafter.

Beyond that, when we focus on specific regions, states, and population groups, sometimes (but far from always) the evidence allows the historian to perceive with a high degree of comfort, but not absolute certainty, general trends and approximate human numbers. It seems fairly

clear, for example, that England's population of roughly 1.4 million around 1100 had risen to about 5 million around 1300 due to a number of factors, including mild weather. During the first half of the fourteenth century that number began to decline slightly due to famine occasioned by the early stages of the Little Ice Age. Worse was to come. With the onslaught of the so-called Black Death in 1347–1348, the population fell precipitously by about 45 percent! In other words, around midcentury England's population was less than 2.75 million and probably declined on a slight downward curve during the next century and a half. It seems equally clear that due to rising agricultural productivity, China's population, including Chinese under alien rule in the north and west, increased from around 80 million in the mid-tenth century to around 100 million in the year 1100 and rose as high as 120 million by 1200, just before the Mongol invasions. In 1290, however, the registered population of China was down to 60 million due to factors already noted in the essay introducing this theme. A century later it was still around 60 million, but unlike England and western Europe in general, a dramatic upsurge was on the immediate horizon.

Regardless of such perceptible trends and approximate figures, we will always have more questions than answers when it comes to both global and regional population fluctuations and numbers during this 500-year period. India's population, for example, defies any consensus among historical demographers. One scholar has posited the theory that around the year 1000 its population stood around 200 million, but by 1500 it had dropped to about 125 million largely due to the great Muslim incursion in the north and resultant wars. Other scholars reject these figures and throw up their hands in despair at ever getting a reasonably accurate picture of Indian population figures before the modern era.

The moral of all of this is: Be wary when presented with population statistics for any society before 1800. We need not go so far as to claim, in concert with the old and trite truism, that there are three levels of lies: lies, damn lies, and statistics. But the problems confronting premodern demographic studies are formidable.

—*Alfred J. Andrea*

What Do We Know about Sub-Saharan Africa's Population?

The reconstruction of sub-Saharan Africa's population during the period from 1000 to 1500 is a daunting challenge. Few states in the region kept what might be considered censuses in the modern meaning of the term. Further, the great variety of environmental and geographical regions means that population densities varied greatly from the savannas to the forests and rain forests. Finally, the fact that remarkably little archaeological research has been done across much of the continent has left the reconstruction of population totals and distribution to be estimated through the process of extrapolating backwards from more modern population totals via estimates of birthrates and mortality. A debate between those who argue that African societies have long utilized high birthrates to overcome high rates of mortality and those who argue that high birthrates are a modern phenomenon dating to the era of the slave trade (or perhaps colonialism) has set much of the tone for research into the subject.

So what do we know about sub-Saharan population in 1000? Rough estimates place the population in 1000 at around 30 million to 45 million and the population in 1500 at around 40 million to 60 million. This low population density compared to other regions of the Old World reflects sub-Saharan Africa's challenging environment, which is typified by soils of low fertility and extensive areas covered by desert or dense forests.

This does not mean, however, that sub-Saharan African populations were not able to find ways to develop the resources that were available to them. Most likely, the bulk of the population was concentrated in three regions: the West African savanna, the Great Rift Valley, and along the East African coast.

The West African savannas, especially along the interior delta of the Niger River, were home to a significant concentration of African peoples. Indeed, by 1000 a thriving matrix of urban trade and manufacturing centers surrounded by relatively fertile lands that produced rice, millet, sorghum, and a variety of vegetable and fruit crops existed across the savannas from the Senegam-

bian Coast (roughly present-day Senegal, Gambia, and Guinea-Bissau) to the region of Lake Chad (in central Africa). The Niger River also provided significant fish resources for surrounding populations.

Another concentration of population existed in the highlands of the Upper Nile and Ethiopia at the northern end of the Great Rift Valley. Here, extremely fertile volcanic soils helped populations thrive through the cultivation of locally developed crops such as teff, ensete, and noog. Like the savannas, this region's density of population gave rise to important urban centers such as Lalibela, the capital of Ethiopia's Zagwe dynasty (ca. 1137–1270).

Farther to the south but also fostered by the rich volcanic soils of the Great Rift Valley, the development of extensive cultivation of bananas and plantains spurred significant population growth in what is present-day Uganda, Rwanda, and Burundi. This region also benefited from the rift lakes' extensive aquatic resources to provide significant sources of protein. Preliminary archaeological studies in the region have suggested that local states developed a system of ever-relocating urban centers that allowed the population to avoid exhausting local environmental resources while still supporting significant concentrations of population. To the east the Golden Age of Swahili society emerged in this period, with dozens of important trading centers developing along the East African coast from present-day Somalia south to Mozambique.

Population densities were much lower in the continent's forest and rain forest regions. Nonetheless, in the period from 1000 to 1500 significant population centers arose in these challenging environments. The kingdom of Benin, in the southern region of present-day Nigeria, and the kingdom of Kikongo, in present-day Angola, are important examples of how human technology, particularly in the form of ironworking, was increasingly allowing humans to carve out more productive agricultural spaces in the African forests and rain forests. Populations of urban agriculturalists were also beginning to establish themselves in the Akan region of modern-day Ghana by the fourteenth century, in part to gain increased access to the region's significant gold reserves. In the period from 1000 to 1500 popu-

lations expanded in the southern African savannas as crops such as sorghum and millet spread and helped diversify the diets of preexisting pastoral lifeways long established in the region.

The population numbers presented here are rudimentary and no doubt will be refined considerably in the future as our knowledge base for African history is improved. This fact highlights the dynamic and ever-changing nature of our understanding of world history.

The Great Afro-Eurasian Pandemic—Did It Originate in Inner Asia?

There are at least three plausible candidates for the original source of the great disease pandemic known as the Black Death of the mid-fourteenth century: the Far East, namely China or India; Ethiopia, or eastern Africa below the Nile River; and Central or Inner Asia, specifically Mongolia. A fourth possibility, that the Black Death originated in Iraq and Kurdistan and spread northward to southeastern Russia, has no support in the historical record. Each of the other three, however, can be buttressed by some kind of contemporary evidence, but the modern scholarly consensus has settled on Mongolia as the most plausible site of origin of the Black Death.

Several European chroniclers of the Black Death were convinced that their affliction began somewhere in the East, and a few of them specified India or China. Native Chinese annals do record a major epidemic in Hopei Province in 1331 and epidemics in other regions beginning in 1345–1346, while the great Muslim travel writer Ibn Battuta mentions a disease epidemic in Madurai in southern India in 1344, from which he himself suffered. But none of the above sources,

THE McNEILL THESIS

In 1976 William H. McNeill published his landmark study, *Plagues and Peoples*, that argued for an expanded role for disease as a major factor in world history. This was not a new idea. Other authors, both ancient and more recent, had made a similar case. But McNeill, with his characteristic breadth of vision, was persuasive in his claim that among the most seismic events of human history were to be counted disease episodes, such as the Black Death of the Middle Ages and the introduction of smallpox and other illnesses by Europeans to the Americas in the early modern period. History, McNeill emphasized, was the casualty of microparasites, such as disease organisms, playing out their symbiotic relationship with macroparasites, humans chief among them, who in turn wreaked their own destructive havoc upon their environment.

In the decades since, other scholars have modified, criticized, and expanded upon McNeill's insights. One theme of this revisionism has been to point out that disease rarely acts alone in bringing change to afflicted societies; rather, it usually works in conjunction with other factors, such as European colonialism and imperialism, which have been largely responsible for introducing disease to other parts of the globe in modern times and have almost always exacerbated the epidemic's impact. Another revisionist complaint about the McNeill thesis is that it too often dwells on the negative aspects of disease's role in human civilization, as opposed to the sometimes surprisingly (and ironic) beneficial outcomes that can result from its mortality. For example, the Black Death certainly disrupted the economy, social relations, and even the psychological assurance and well-being of Europeans during the late Middle Ages, but it also may have provided a much-needed stimulus for enhanced fertility, improved sanitation and public health measures, and technological advances in response to the resulting demographic crisis.

It may well be the questions, rather than any answers, that McNeill posed in *Plagues and Peoples* that will prove to be his most lasting contribution to the study of the history of disease.

—John Aberth

due to the brief nature of their references, positively identify these local disease outbreaks as the same one that spread to Europe and Southwest Asia by late 1347 and 1348. Furthermore, the most likely trade route for the dissemination of plague westward from the Far East was across the Iranian plateau and up the Persian Gulf along the Red Sea and through modern-day Iraq along the Tigris River, yet the available evidence points to the disease spreading to these regions from the north and west, namely from the Crimea or southern Russia and the Mediterranean coast rather than from the south and east. An Ethiopian source for the Black Death is proposed in two contemporary plague treatises written by the Spanish physicians Jacme d'Agramont and Ibn Khatima. However, native Ethiopian sources fail to confirm this opinion, and it seems likely to be derived from a traditional belief that major epidemics in ancient times, such as the Plague of Athens of 430–426 BCE and the Plague of Justinian of 541–542 CE, originated in Africa.

The preponderance of evidence in fact points to our third candidate, Mongolia, as the real home of the Black Death. This is the only region to yield a variety of source material, including contemporary chronicles, archaeological finds, and modern epidemiological studies, in support of its claim. It also forms the heartland of perhaps the greatest overland trade route of the late Middle Ages, linking East to West across the vast Mongol empire, that was made famous by the travels of Marco Polo, among others.

Medieval chroniclers who were most strategically placed to report on the geographical distribution of the Black Death—Muslim authors from Palestine or Egypt, at the hub of shipping throughout the Mediterranean and points East—unequivocally point to Mongolia as the origin of the disease. Ibn al-Wardi, writing from Aleppo in northern Syria in 1348, asserts that the plague “began in the land of darkness,” a reference to the homeland of the inveterate Mongol enemy of his Mamluk rulers. Moreover, al-Wardi claimed that plague had been present in this region for 15 years (i.e., since 1332–1333) and that it spread to China and India from there. Another Muslim author, Ibn al-Maqrizi, writing from Cairo in the fifteenth century, claims, on the basis of information from Uzbekistan in Central Asia, that

the Black Death began “in the land of the Great Khan” in 1341. Several other contemporary authors, who, albeit less well placed, probably derived their knowledge from traveling merchants, also placed the origins of the Black Death in the land of the “Tartars” or the “Khitai.” “Khitai” clearly refers to the former Jin empire of northern China, which the Mongols conquered in 1215; “Tartars” likewise referred to the Mongols. These authors include the Florentine chronicler Giovanni Villani as well as the Spanish Moorish physicians Ibn Khatima and Ibn al-Khatib.

Even more convincing evidence of a Central Asian origin of the Black Death was discovered in the nineteenth century by a Russian archaeologist, Daniel Chwolson, who uncovered a mass grave in the region of Lake Issyk Kul in present-day Kyrgyzstan dating to 1338–1339; three of the headstones at the site contained Nestorian Christian inscriptions stating that ten of the interred had died of plague, or the “pestilence.” Finally, the research of Dr. Wu Liande, a Chinese bacteriologist who headed his country’s response to two major outbreaks of pneumonic plague in Manchuria in the first quarter of the twentieth century, confirmed that the Central Asian steppes harbored an ancient endemic reservoir of the disease among the local tarabagan, or marmot, rodents.

All this persuades most historians that the origins of the disease that was to prove to be the watershed event in Europe and the Middle East throughout the late Middle Ages are to be found in the Central Asian plateau, across which goods and pathogens traveled freely ever since the thirteenth century. Ironically, the Mongol domination of overland routes from Asia to Russia that made possible the revival of the Silk Road was coming to an end by the time the Black Death made its fateful arrival in the West.

The Plague Arrives in the Levant

All evidence points to the Black Death coming to the Levant, or the region of the eastern Mediterranean, from southern Russia as early as 1346 or 1347. Our best source for the dissemination of plague in this region is the Muslim author Abu Hafs Umar ibn al-Wardi, who was writing from Aleppo in northern Syria in early 1348 just as the disease arrived in Syria-Palestine. After ascribing the origins of the plague to “the land of darkness,” probably Mongolia, al-Wardi traces its route westward to the Crimea, or the region of the Black Sea, and from there on to Byzantium and Cyprus. But then the plague jumps to the southern end of the Levant, to Alexandria in Egypt, before moving northward through Gaza, Ascalon, Acre, Jerusalem, Beirut, and Damascus, before ending up in Antioch and Aleppo at the northern end of Palestine. The Black Death therefore did not take a straightforward, direct route from north to south in the Levant, according to al-Wardi, but, as everywhere else, seems to have closely followed trade and shipping routes.

Al-Wardi’s testimony is confirmed by other authors. Two Byzantine chroniclers, Nicephorus Gregoras and the former emperor John VI Kantakouzenos, report that the plague arose in Scythia, or southern Russia, in 1346 or 1347 and from there spread throughout the Aegean. Meanwhile, the Egyptian author Ahmad Ibn Ali al-Maqrizi claims that the Black Death arrived in Egypt by the early autumn of 1347. This would place the disease on the same timetable as its arrival in southern Italy; indeed, the same Italian merchants, whom the Piacenzan chronicler Gabriele de Mussis famously describes as besieged by plague-infested corpses lobbed into the town of Caffa on the north coast of the Black Sea by the Mongols, could equally well have carried the

➤ ABU HAFS UMAR IBN AL-WARDI, *ESSAY ON THE REPORT OF THE PESTILENCE*

“The plague frightened and killed. It began in the land of darkness. Oh, what a visitor! It has been current for fifteen years. China was not preserved from it nor could the strongest fortress hinder it. The plague afflicted the Indians in India. It weighed upon the Sind [present-day Pakistan]. It seized with its hand and ensnared even the lands of the Uzbeks. How many backs did it break in what is Transoxiana [present-day Uzbekistan and neighboring regions]! The plague increased and spread further. It attacked the Persians, extended its steps toward the land of the Khitai [northern China, or Cathay], and gnawed away at the Crimea. It pelted Rum [the Byzantine empire] with live coals and led the outrage to Cyprus and the islands. The plague destroyed mankind in Cairo. Its eye was cast upon Egypt, and behold, the people were wide-awake. It stilled all movement in Alexandria. The plague did its work like a silkworm. It took from the tiraz [embroidered silk] factory its beauty, and did to its workers what fate decreed. . . .

Then, the plague turned to Upper Egypt. It, also, sent forth its storm to Barqa [present-day Ashdod in Israel]. The plague attacked Gaza, and it shook Ascalon severely. The plague oppressed Acre. The

scourge came to Jerusalem and paid [with the souls of men] the zakat [a mandatory tax of 2.5 percent on all Muslims]. It overtook those people who fled to the al-Aqsa Mosque, which stands beside the Dome of the Rock. If the door of mercy had not been opened, the end of the world would have occurred in a moment. It, then, hastened its pace and attacked the entire maritime plain. The plague trapped Sidon and descended unexpectedly upon Beirut, cunningly. Next, it directed the shooting of its arrows to Damascus. There the plague sat like a king on a throne and swayed with power, killing daily one thousand or more and decimating the population.”

Michael Dols, “Ibn al-Wardi’s *Risalah al-Naba’ ‘anal-Waba’*,” a Translation of a Major Source for the History of the Black Death in the Middle East,” in *Near Eastern Numismatics, Iconography, Epigraphy and History: Studies in Honor of George C. Miles*, edited by Dickran K. Kouymjian (Beirut: American University of Beirut, 1974), 448–450.

infection southward to Egyptian ports as eastward to their homeland. Alexandria, for example, was an important port of call for the Christian maritime trade plying the Mediterranean from the Black Sea and Constantinople. As a matter of fact, al-Maqrizi relates how a slave ship whose sailors and cargo were decimated by the Black Death docked at Alexandria’s harbor, whereupon the remaining survivors died. The plague’s subsequent progress from south to north through Palestine that is recorded by al-Wardi is likewise reported by the great Muslim traveler Ibn Battuta.

The details of the Black Death’s arrival and advance throughout the Levant are an important piece of evidence for our knowledge about the disease. Some scholars have been puzzled as to how bubonic plague could have spread as quickly as the chroniclers record it to have done, given that its principal animal carrier was the black rat, normally not a migratory creature. Yet it is

clear from the evidence of the plague’s dissemination in the Levant that the transmission of the disease was not always so straightforward as a simple rat-to-human contact would make it seem. Despite the fact that northern Syria was far closer geographically to the Crimea and the Aegean than Egypt, the plague struck Egypt first and then traveled northward from there. Contemporaries did indeed observe this strange, atypical migration of the disease, sometimes skipping whole regions before coming back to hit them later, and compared it to how the plague almost seemed to be playing with its victims, moving as if on a chessboard. The most likely explanation is that the insect vector of bubonic plague, the rat flea, can survive for relatively long periods—at least 80 days—away from its host in a comparable environment, such as animal fur, that is transported from place to place as merchandise. In fact, furs were one of the main exports of trading factories at Tana and Caffa operated

by Italian merchants on the north coast of the Black Sea; they were as much in demand as fashion accessories in Mamluk Egypt as in Europe. Of course, it is perfectly possible that plague-bearing rats were yet another cargo on board that then somehow scampered ashore perhaps along mooring ropes, as suggested by one historian, once the ship had weighed anchor in port. But the experience of plague in the Levant compellingly suggests that the disease could travel equally well without its animal host all along the prosperous but deadly trade routes of the eastern Mediterranean.

The Populations of the Middle East and North Africa before and after the Great Pandemic

The demographic impact of the Black Death upon North Africa and the Middle East is harder to measure than in the case of Europe. Yet the *diwans*, or administrative bureaucracies, of the Muslim lands kept records just as good as, if not better than, any of the states in Italy, England, or elsewhere in the West. For instance, during the plague epidemic of 1429–1430 in Egypt, which was said to be comparable in its mortality to the initial onslaught three-quarters of a century earlier in 1348–1349, three kinds of records were kept of the daily death rate in Cairo: the number of dead who left taxable legacies that were reported to the local diwan, the number of dead for whom funerals were held at the various mosques throughout the city, and the number of dead who were counted as they were carried out of the city gates for burial. Since no single one of these methods on its own gives the total death rate for the city, chroniclers had to multiply each figure by some factor that would reflect what they believed was its proportionate repre-

sentation of the whole. Yet these techniques were also much in evidence during the great pandemic of 1348–1349 and acquired wide fame. Even a chronicler such as Gabriele de Mussis, writing from as far away as Piacenza in Italy, heard of how the sultan was able to count the dead in Babylon (Egypt) by recording in his register the death taxes he received, which yielded the fantastic figure of nearly half a million dying in just three months in 1348.

All this should make for a death toll as accurate as any to be found in Europe, yet we are forced to rely on secondhand accounts, such as the chronicle of Ahmad Ibn Ali al-Maqrizi, as our only record of such figures. A broader picture of population loss from the plague is available from the *cadasters*, or tax surveys, that were periodically conducted throughout the various provinces of Egypt, with one dating to 1315 and then revised from circa 1375 to 1420. Even here, however, we must rely on abbreviated versions available in the chronicles rather than on original sources. Last, we can turn to impressionistic statements on the number dying daily from the plague that were made by the Arab chroniclers themselves, who were perhaps no less prone to exaggeration than European writers but who we know had access to the more reliable statistical sources mentioned above.

The demographic conclusions to be drawn from such problematical evidence are therefore completely lacking in the precision and finality of such modern data as census returns (which themselves are never totally accurate). Thus, the best estimates are that Egypt had a population before the Black Death of between 4 million to 8 million, while the populations of Syria, Palestine, Lebanon, and Transjordan (present-day Jordan), also administered by the Mamluk dynasty at this time, numbered between 900,000 and 1.2 million on the eve of the Black Death. Based on the cadastral surveys, the population in Egypt seems to have risen continuously from the twelfth century until at least 1315, when it was at its height. Unlike in Europe, there seems to have been no demographic decline setting in during the early decades of the fourteenth century just prior to the plague. On the contrary, population continued to grow in the Middle East until it was abruptly halted by the disease.

► EXCERPT FROM AHMAD IBN ALI AL-MAQRIZI, *A HISTORY OF THE AYYUBIDS AND MAMLUKS*, FIFTEENTH CENTURY

Ahmad ibn Ali al-Maqrizi wrote numerous works of history from 1418 until his death in 1442. His *History of the Ayyubids and Mamluks* describes the arrival and impact of the Black Death upon Egypt and in particular upon its capital, Cairo. Although written more than half a century after the first outbreak of the plague in 1347–1348, al-Maqrizi's history is thought to incorporate earlier sources, now lost.

“At the start of du l-qada [January 21], Cairo had become an abandoned desert, and one did not see anyone walking along the streets. A man could go from the Port Zuwayla to Bab al-Nasr without encountering a living soul. The dead were very numerous, and all the world could think of nothing else. . . .

“They made a count of the number of persons [who died] from those whose [names] had been recited in funeral prayers in the oratories of the suburbs just outside of Bab al-Nasr, the Zuwayla Gate, the Burnt Gate, the Citadel esplanade, [and] in the oratory of the Lion Slayer opposite the Qawsun Mosque: in two days, they counted 13,800 dead, not counting those who died in the markets, in vacant lots, outside the River Gate, those who had been abandoned in front of the

shops or in the Husayniya quarter and the Ibn Tulun Mosque, and, one can well understand, those who had died in their own homes and whose burial had been delayed.

“According to another estimate, 20,000 dead had been [counted] in only one day. The count [based] on the funerals in Cairo, during the months of saban and ramadan [November–December], yields a figure of 900,000, still not counting the deaths in vacant lots, as well as those in the Husayniya and Saliba quarters, and in the streets of the immediate suburbs of Cairo, which would more than double [the above count]. The number of [funeral] biers was around 1,400, [but] then there are those [bodies] that they missed, and they [also] carried the cadavers on the trellises [and] window shutters of shops and on simple boards, and in addition, they [often] transported two or three cadavers on only one bier or on only one board.”

—John Aberth

Source

Gaston Wiet, “La Grande Peste Noire en Syrie et en Egypte,” *Etudes d’orientalisme dédiées à la mémoire de Lévi-Provençal*, 2 vols. (Paris: G.-P. Maisonnouve et Larose, 1962), 1:376–377.

The Black Death dealt a crippling blow to the Mamluk populations in Egypt and Syria from which they did not recover until well after the Middle Ages, perhaps not even until the nineteenth century. Estimates made by European observers in the late eighteenth and early nineteenth centuries, some based on census returns, put the population of Egypt at around 2 million, down from as much as 8 million prior to the plague, and the population of Cairo, which was perhaps 500,000–600,000 before the Black Death, at 250,000. Thus, population in the region is thought to have continued to decline even after the region was conquered by the Ottoman empire in 1517.

During the first outbreak of the Black Death in Cairo, which lasted five months from September 1348 to January 1349, the chronicler al-Maqrizi, claiming to base his figures on a count

of funerals at various oratories throughout the city, counted up to 20,000 dying a day at the height of the epidemic and a total of 900,000 dead, which far surpasses the total population estimated for Cairo even before the plague. A more sober estimate for plague mortality in Cairo that was made during the epidemic of 1429–1430 and was based on the three statistical methods mentioned above gives a daily death rate of just over 2,000 per day at the height of the disease and a total loss of 100,000 people, representing a fifth or sixth of Cairo's preplague population. Historians have therefore revised Cairo's loss during the plague of 1348–1349 to a peak daily mortality of at most 10,000 and a total population loss of 200,000, representing anywhere from one-third to two-fifths of the city's preplague numbers. In Damascus, the leading city in Syria, where the first plague outbreak

lasted from June 1348 until March 1349, the daily death rate reached 1,000–2,000 at the epidemic's height, and 30,000 out of 80,000 in total died, a decline of 38 percent. If we accept al-Maqrizi's general estimate that the Black Death of 1348–1349 wiped out one-third of the population of Egypt and Syria, then Egypt's population declined by as much as just under 3 million, and Syria's population declined by as much as 400,000. The cadastral surveys, which record an average 12 percent decrease in tax revenues from before the Black Death to the third quarter of the fifteenth century, have been translated into a rural population decline for Egypt of 20–30 percent, although this is considered by most historians to be far too low.

In general, the plague, due to its repeated occurrences throughout the latter half of the fourteenth century and throughout the fifteenth century, is held largely responsible for a sustained population decline in the Middle East and North Africa that, unlike in Europe, did not begin to recover as the Middle Ages came to an end. However, other factors undoubtedly contributed to this decline besides plague, and in Egypt these included famine, flooding, and emigration (despite Muslim religious taboos against flight during a plague outbreak). This had quite severe agricultural and economic impacts that contributed substantially to the tumultuous end of the Mamluk dynasty in Egypt and Syria by the early sixteenth century.

China's Population Shifts

Today Asia is home to a significant portion of the world's population, as it was in the year 1000. During the era of the Tang dynasty (618–907), China had a population of approximately 60 million. Despite the decades of chaos and disunity that followed its collapse, the population rose to

about 100 million by the year 1100. Although such periods of disunity were not unusual for China, the dominant Han ethnic and cultural group longed for the return of a unified central government. In 960 the vast majority of Tang territory was conquered by the ethnic Chinese Song dynasty (960–1276), but the far north remained beyond its reach. Because the non-Chinese Liao, Xia, and Jin states were a permanent threat, the Song elected to pay tribute to their northern neighbors. Despite the payments, in 1127 the Jurchen (Ruzhen), who had created the Jin empire, conquered all of northern China. Historians think that the Song may also have been weakened due to a cooling trend in the world's temperatures that caused crop failures.

The Song court fled south, where previously hot temperatures and diseases such as malaria flourished in the swampy lands surrounding the Yangzi River (also known as the Changjiang, or Long River). Despite its territorial losses the Song still ruled 60 percent of China's population, and the country thrived. It benefitted from the world's first commercial revolution, even though more than 90 percent of the Song population was composed of peasants who lived in poverty and rarely escaped the cycle of borrowing from landlords or moneylenders. Although many Han Chinese still pined for the lost north, they came to appreciate the benefits of the Yangzi River Valley. The northern Yellow River was laden with loess, or wind-blown silt, and was hard to navigate compared to the Yangzi. Using the Yangzi for transportation of goods not only lowered costs but also helped to expand market distribution. The continued shift of the population south that initially began in the eighth century resulted in the draining of the muddy lands for settlement and farming. Soil and weather conditions, the introduction of a new strain of rice from Vietnam, and seed hybridization resulted in double-cropped and, at times, triple-cropped rice. Before this most farmers were self-sufficient, buying few items other than salt. Now, farmers who no longer had to use the bulk of their land to grow grain to eat or for taxes or rent could specialize in high-value crops such as lichee, lotus root, and tangerines. Farmers also had more time to produce handicrafts, and some left farming completely.

➤ DISEASE DATA FOR YUAN CHINA

China's Yuan dynasty (1279–1368) was only one part of the Mongol empire. It is speculated that the nomadic Mongols suddenly burst forth from the steppe north of China and south of Siberia in search of new grasslands due to climatic changes that resulted in a dramatic drop in temperatures. Traditionally, Mongol tribes roamed the steppe grasslands with their flocks of horses and sheep. Unfortunately, animal husbandry also facilitates the spread of disease due to the transfer of animal pathogens to humans. Hence, when Chinggis Khan unified the Mongol tribes, captured northern China, and moved west toward Europe, disease traveled with him. The Mongols are associated with terror and warfare in their empire, which encompassed eastern Europe and the Middle East, but the Pax Mongolia that facilitated trade along the Central Asian Silk Road and other sea and land trade routes proved equally deadly. Epidemics of diseases such as the bubonic plague (believed to be the Black Death), smallpox, and measles increased in number. Spread by fleas that live on rats (rats can themselves build up an immunity), the plague is estimated to have killed close to half of Europe's population. The Mongols were not immune to the scourge, for which there was no antidote or cure. Although entire towns and peoples were decimated through warfare by the Mongols in Yuan China, diseases such as the plague also took a toll. Tax revenues of the Yuan fell as the Chinese people were devastated by the epidemic, which, it is estimated, claimed the lives of 90 percent of Hubei Province's population alone in 1331. Yuan China's population decreased by an estimated 30 million to 40 million or more. There is no doubt that disease contributed to the Yuan dynasty's collapse.

—Tracy Lee Steele

The population of the Southern Song soared, perhaps surpassing 100 million. This may be attributed to many factors, such as sufficient foodstuffs and improved diets, but ironically the number of epidemics increased. Trade and travel facilitate the spread of disease, but so do wet rice cultivation and animal husbandry. Untreated human excrement was often used in fertilizers, particularly rice paddies where shoeless farmers

toiled. Not surprisingly, the number of chronic infectious and parasitical diseases such as schistosomiasis, which is caused by waterborne blood flukes, increased. Close contact between domesticated animals and humans also allowed animal parasites to contaminate humans beings, as is believed to be the case with smallpox (from cattle) or the flu (from pigs and ducks). Hence, the South recorded the highest incidence of epidemics in China in this period. Still, the population grew until the time the Mongols overran the Song and established the Yuan dynasty (1279–1368), when the population is believed to have declined by at least 30 million and quite possibly much more, as much as by 50 percent.

A great deal is known about the people of the Ming dynasty (1368–1644) due in large part to the Yellow Registers. First compiled in 1381, they included information on all household residents including name, age, ancestral home, and occupation as well as land and animal stock holdings. According to the register, China's population was then between 60 million and 65 million, but many scholars think that the actual number was higher. This government effort was not a census but was used to bind all the households into units of 110 and subunits of 11 in order to control the people who were primarily farmers and to ensure payment of taxes and the labor service required by the government. Needless to say, many people may have avoided registration to avoid payment, and girls may also have been overlooked. Hence, these population numbers could be considerably higher. Ultimately, peace and agricultural improvements resulted in a doubling of Ming China's population to between 150 million and 200 million.

Europe's Population, 1000–1347

Population trends for medieval Europe, even before the major disruption of the Black Death, remain elusive. Perhaps the best estimates exist for England, where the most records survive, but even here demographers have only two kingdom-wide surveys of population to go on: the famous Domesday Book of 1066 and the Poll Tax returns of 1377, taken after the country had suffered no less than three major bouts of plague. These and other records have generally led scholars to conclude that England and Europe experienced a population boom throughout most of the thirteenth century, but then the population started a long, slow decline from about 1290 until the onslaught of the unprecedented demographic crisis of the Black Death beginning in 1348. But these conclusions are subject to much uncertainty and to the necessity of making broad assumptions.

More useful perhaps are local surveys of population, particularly in assessing demographic trends over the course of several decades. But by their very nature, local trends, especially when compared with each other, can appear contradictory and are hard to extrapolate to a broader geographical region. For example, tithing records for six manors in Essex, England, suggest that population crested at the turn of the fourteenth century and then commenced a steady decline from the time of the Great Famine beginning in 1315; however, comparable records from two manors in Worcestershire and northeastern Nor-

THE POSTAN THESIS

The Cambridge historian M. M. Postan first published his thesis that Europe's population was destined to decline by the early fourteenth century in an essay published in the *Economic Historical Review* in 1950. Essentially, Postan revived the ideas of the great English economic theorist Thomas Malthus, who postulated in 1798 that population growth, since it increases at an exponential rate, would always outstrip a society's food supply and therefore needed to be brought back into balance through either positive checks (such as disease) or through preventative checks (such as human decisions about birthrates). However, Postan believed that a Malthusian crisis by circa 1300 was greatly exacerbated by the fact that the thirteenth century's population boom was mostly fueled by *assarting*, or the conversion of wasteland into arable land. These lands quickly became exhausted, Postan argued, and since medieval farmers had no other ways of increasing yields, this soon led to a subsistence crisis, as clearly indicated by the arrival of the Great Famine in 1315. Although Postan's thesis held sway during the 1950s and 1960s, it began to be challenged in 1976 by the Marxist historian Robert Brenner. Most recently, scholars have attacked Postan on various grounds, which include evidence of regional variations in medieval agricultural production, the difficulty of determining how wastelands should be defined, and the fact that the Great Famine was largely due to the unpredictable vagaries of the weather.

—John Aberth

folk point to a nearly opposite trend, one of modest population growth in the decades in between the famine and the onset of the Black Death. At the very least, historians seem to agree that medieval Europe's population, even if it did grow during the early fourteenth century, did so at a far less robust rate than during the first three quarters of the thirteenth century.

The most memorable demographic event to occur in northern Europe before the plague was the Great Famine, which struck in 1315 and persisted, in some areas, until as late as 1322. Demographic evidence from England as well as from Flanders on the Continent indicates that mortality

losses due to the famine were on the order of 10–15 percent. This was significantly higher mortality than normal, yet historians of the famine do not consider it insurmountable, to the point that population could not recover to its previous levels, or even higher, before the onset of the plague. In other words, the mortality caused by famine had no long-lasting impact on overall population trends in the early fourteenth century. Nonetheless, contemporary chroniclers were certainly impressed by the famine, with some even reporting cases of a desperate resort to cannibalism or to eating grass and the raw carcasses of cattle.

On the whole, there is no conclusive evidence that the Black Death was an inevitable component of a downward trend in Europe's population prior to 1348, as the Postan Thesis would have it. Much, if not most, of the population decline before the plague can be attributed to a single demographic crisis, the Great Famine of 1315–1322. The Black Death should therefore be seen as a quite unique demographic event in medieval Europe's history that struck like a hammer blow on an unsuspecting population that may otherwise have expected to continue to grow during the rest of the fourteenth century.

Europe's Black Death—Origins and Spread

There is a famous story told by the Piacenzan chronicler, Gabriele de Mussis, about how the Black Death first came to Europe from Asia. Sometime in the year 1346, according to Mussis, a Mongol army, undoubtedly under the command of the Kipchak khan of the Golden Horde,

Janibeg, besieged some Genoese merchants holed up in Caffa (present-day Feodosiya) on the northern coast of the Black Sea. In an apparent stroke of good fortune for the defenders, the Mongols suddenly got the plague; unfortunately for the Italians, however, the besiegers decided to lob the dead bodies of their comrades into the town in what is perhaps the first recorded instance of germ warfare. Although it is hard to believe that plague-carrying fleas could survive the violence of being catapulted, it is nonetheless quite likely that plague first came to Europe from this region. The trading factories of Caffa and Tana on the Black Sea were important suppliers of expensive animal furs, such as ermine and marten, that were much in demand among the well-to-do in Europe. But in the year of the plague, such furs became a deadly luxury when infested with fleas.

Several chroniclers besides Mussis continue the tale with how some Genoese galleys, variously recorded as two, three, or four in number, subsequently made the more than 2,000-mile (3,220-kilometer) journey back home to Italy, where they imported disease as part of their cargo. Louis Sanctus, writing to a friend in April 1348 from Avignon near the southern coast of France, mentions that these Genoese refugees first infected Greece and then Sicily and finally their home port of Genoa on the Italian mainland, where "they were expelled from that port with flaming arrows and diverse engines of war, because anyone who dared touch them or have any business dealings with them immediately died." From Italy, the Genoans next docked at Marseilles, where, according to Sanctus, they infected the inhabitants there and last were seen making their way along the coast of the southern Mediterranean toward Spain. The Greek chroniclers Nicephoras Gregoras and John VI Kantakouzenos confirm that plague came to Constantinople in the spring of 1347, while the Sicilian chronicler Michele da Piazza reports that no fewer than 12 Genoese galleys, whose sailors carried the disease "down to the very marrow of their bones," called at the port of Messina in October of the same year. There is thus broad agreement among the chroniclers that Italy, and Sicily in particular, were the first ports of call for the plague in Europe.

► GABRIELE DE MUSSIS, *HISTORY OF THE PLAGUE*

Gabriele de Mussis, a lawyer from Piacenza in Italy, wrote a *Historia de Morbo (History of the Plague)* sometime before his death in 1356. His account is considered one of the best sources on the arrival of the Black Death in Europe.

"In the year of our Lord, 1346, in eastern parts, an infinite number of Tartars [Mongols] and Saracens succumbed to an inexplicable disease and to sudden death. And there, the broadest regions, infinitely large provinces, magnificent kingdoms, cities, castles, and places that once had been full with a great multitude of men . . . were in a short space of time emptied of their inhabitants. . . . Behold how the infidel Tartar races, suddenly pouring in from every side and surrounding the city of Caffa, besieged the Christians shut up there, a siege that lasted for nearly three years. . . . And behold, the whole army of the Tartars was laid low by the disease, so that it seemed that every day, thousands upon thousands were wiped out, as if by arrows raining down from the sky. . . . The Tartars . . . abandoned the siege as if thunder-struck and stupefied on every side, recognizing

that there was no hope of escaping death. But they ordered that their dead be loaded onto their catapults and lobbed into the city of Caffa, so that the cadavers might kill everyone with their intolerable stench. Thus it seemed as if mountains of the dead were thrown in, so that the Christians . . . could not escape this disaster, even though they consigned as much of the dead as they could to the waves of the sea. And soon the whole air was infected and the water poisoned by the putridity of the corpses, and the stench grew to the point that hardly one out of every thousand even attempted to escape what remained of the Tartar army. And those who had been poisoned carried the poison to others wherever they went, infecting all, both places and men, with the disease by look alone."

—John Aberth

A. W. Henschel, "Document zur Geschichte des schwarzen Todes," in *Archive für die gesamte Medicin*, edited by Heinrich Haeser II (Jena, 1842), 48–49. [Translated by John Aberth.]

On the basis of other regional chronicles, historians have reconstructed the subsequent path of the Black Death across Europe. After making landfall in Sicily and perhaps Genoa and Marseilles in late 1347, the plague began its terror in earnest in 1348, when it spread throughout Italy, France, and Spain and invaded Switzerland, Austria, England, and perhaps Denmark. By 1349–1350 plague had come to all of Germany and eastern Europe, the Low Countries, all of the British Isles, and all of Scandinavia. It reached Russia (probably coming by way of Sweden) in 1352, while the silence of the records indicates that it skipped over Poland and Bohemia.

Some historians have doubted whether the Black Death was largely bubonic plague, since, they argue, the speed of its spread across Europe precludes a rat-borne disease. Yet it can live for 80 days without an animal host and thus travel independently of rats in animal furs, wool packs, and other merchandise. Indeed, the path of the Black Death seems to closely follow in the wake of the trade routes crisscrossing Europe.

Burying plague victims of Tournai, 1349, from the *Annals* of Gilles de Muisit, 1352, Abbot of Saint-Martin. (Snark/Art Resource, NY)

An additional factor contributing to the plague's rapid spread—and one that is all too readily discounted by many historians—is the possibility that the more deadly pneumonic plague could erupt and spread independently of the bubonic variety. For example, Michele da Piazza describes the first victims in Sicily, the inhabitants of the port city of Messina, as coughing up “bloody sputum” and dying within three days, symptoms that are typical of pneumonic plague. He then goes on to affirm that the Messinese who fled the city proceeded to spread the disease throughout Sicily with their “infectious breath.” A rapid virulent spread therefore seems not inconsistent with an identification of the Black Death with plague, especially in all its insidious forms.

The Demographic Impact on Europe, 1347–1500

One of the most frequently heard shibboleths about the plague—endlessly repeated by historians like some mind-numbing mantra—is that the Black Death, in its first outbreak of 1347–1350, wiped out only a third of Europe's population. This is, quite simply, wrong. Its only support comes from perhaps the least reliable demographic source for plague mortality: the English inquisitions post mortem, which were conducted after the death of a landlord in order to determine who should inherit an estate. These give us a death rate of 27 percent for England during the Black Death, yet they are limited to a very narrow and privileged portion of the population, a sample of just over 500 potential plague victims, who were at undoubtedly lower risk of

► THE STATUTE OF LABORERS

One of the more telling records of the social and economic dislocations created by the first outbreak of the Black Death in 1348–1349 is the labor laws that were enacted by England, France, the kingdoms of Castile and Aragon in Spain, and several cities in Italy. Perhaps the most famous of these laws is the Statute of Laborers that was enacted by the English Parliament in 1351, building upon the earlier Ordinance of Laborers that had been enacted by the king and council in 1349, when Parliament was not in session due to the plague. The preamble of the statute, printed below, attests to the new economic realities created by the extraordinary mortality among the population and to the government's persistent efforts to respond.

“It was lately ordained by our lord the king, with the assent of the prelates, nobles and others of his council against the malice of employees, who were idle and were not willing to take employment after the pestilence unless for outrageous wages, that such employees, both men and women, should be obliged to take employment for the salary and wages accustomed to be paid in the place where they were working in the 20th year of the king's

reign [1346], or five or six years earlier; and that if the same employees refuse to accept employment in such a manner they should be punished by imprisonment, as is more clearly contained in the said ordinance. Whereupon commissions were issued to various people in each county to make inquiry and punish all those offending against the ordinance. And now the king has been given to understand by a petition of the Commons in the present Parliament that the said employees, having no regard to the said ordinance but rather to their own ease and exceptional greed, withdraw themselves to work for great men and others, unless they are paid livery and wages double or treble what they were accustomed to receive in the said 20th year and earlier, to the great damage of the great men and the impoverishing of all the Commons, for which the said Commons pray for remedy.”

—John Aberth

Source

A. Luders et al., *Statutes of the Realm, 1101–1713*, 11 vols. (London, 1810–1828), 1:311.

contracting the disease. The inquisitions also do not record the deaths of all members of a family. Behind every surviving heir to a vacant estate, there may have been several others whose deaths went unrecorded.

Perhaps the most reliable demographic records for plague mortality are bishops' registers, which record vacancies that occurred in every parish church within a diocese. These records were compiled conscientiously by the most literate members of medieval society, and ten such registers survive from the plague period in England from dioceses distributed throughout the land. They collectively yield a death rate of 45 percent during the first outbreak of the Black Death in England in 1349. Manorial records from England, which record the death dues, known as *heriots*, paid by the families of deceased serfs to their lords register mortality rates ranging from 40 percent to 70 percent on manors across the country, including those in Cornwall, Somerset, and Worcestershire in the west; Suffolk, Nor-

folk, and Cambridgeshire in the east; Hampshire, Wiltshire, Essex, and Oxfordshire in the south; and Durham in the north.

What little evidence survives from the Continent suggests that death rates there were no lower than in England. For the first plague period from 1348 to 1350, a variety of records that include parish registers, tax assessments, household census returns, scribal records, and bishops' registers reveal death rates ranging from 45 percent to 68 percent at Givry and Albi in France, San Gimignano in Italy, and Perpignan and Barcelona in Spain. Given all this evidence, the average mortality for all of Europe during the first outbreak of the Black Death should be revised upward to around 50 percent.

For the next 150 years after the first arrival of the Black Death in Europe in 1347–1348, population throughout England and the Continent held steady and may even have slightly declined. Recovery of demographic numbers was scarcely possible in an era nicknamed the “Golden Age of

the Germ.” In England, further national outbreaks of plague occurred in 1361, 1369, 1374–1379, and 1390–1393; as many as 11 more major epidemics struck during the fifteenth century, particularly during the 1420s, 1430s, 1460s, and 1470s. Mortalities during these subsequent outbreaks were considerably lower than in 1348, but cumulatively over time they added up to some striking population losses. For example, tax records that survive from Italy attest that by 1427, four cities, including Florence, San Gimignano, Pistoia, and Prato, suffered population declines from anywhere between 62 percent and 75 percent. Meanwhile, farther north in eastern Normandy, *monnéage* (hearth tax records) point to an astounding cumulative decline of 130 percent between 1347 and 1442. Furthermore, the detailed obituary lists for Christ Church Priory in Canterbury, England, record that life expectancies for even these exceptionally well-cared-for monks reached a nadir of 23 years at birth, largely due, it seems, to the occurrence of no less than 27 higher-than-normal mortalities throughout the fifteenth century.

The pursuit of a complete and accurate demographic picture of Europe during the time of the Black Death is no mere academic exercise. Only extraordinarily high mortalities can explain the dramatic social and economic dislocations that afflicted Europe during the latter half of the fourteenth century and throughout the fifteenth century.

Artists and the Cult of Death in Western Europe

There are many ways to measure the impact of the Black Death upon Europe. One approach is to examine the art produced by the generation

immediately following the plague of 1348–1350, even if its themes make no literal reference to disease or death. The limitations of this approach stem from the difficulties in dating medieval works precisely—and thus establishing the Black Death as a definitive break in a genre—and by the subjective nature of interpretation. In one view, the Black Death brought the Early Renaissance spirit of innovation to a grinding halt through the deaths of its leading artists, inaugurating a more conservative and rigid school. But in another view, the plague was a positive force, either by reinforcing faith through a refocused depiction of traditional plague saints, such as Saint Roch, or by providing a major impetus to the Renaissance theme of individualism. Many patrons felt impelled to commission portraits to be remembered in the face of mass death.

Perhaps a more rewarding approach to this subject is to focus on art and literature, whose themes are intimately connected with and thus highly revealing of late medieval attitudes toward death. In particular, the emphasis here is on artistic and poetic depictions of a dessicated and decaying corpse, a type of representation known as the macabre, or *memento mori* (remembrance of death). Of all artistic representations, this genre, although its origins predate the Black Death, is most closely associated with the plague. Two of its most emblematic themes are the Dance of Death and the *transi* tombs.

It is quite possible that a dance associated with the figure of Death first arose in conjunction with the Black Death of 1348. The *Great Chronicle of France* testifies to a dance performed in that year to ward off the plague. Other chronicles report that in 1374 a dancing mania seized hundreds of people in German and Flemish towns. The people periodically interrupted their dance to fall to the ground and allow onlookers to trample on them in the belief that this would cure them of their “extreme oppression,” although it is nowhere stated that this was the disease. These people may have been exhibiting or masking through dance one of the neurological symptoms of the bubonic plague, called chorea, or St. Vitus’s Dance, that produces involuntary muscle contractions. The dances also indicate that the plague may have engendered mass psychosis.

➤ A DISPUTACIOUN BETWYX THE BODY AND WORMES

A variation on the debate poems between the body and soul that were popular during the Middle Ages, *A Disputacioun betwyx the Body and Wormes* is unique in that it is illustrated by marginal water-color drawings, the first of which shows the tomb of a great lady, while her shrouded cadaver underneath is riddled with what look like worms, frogs, and salamanders. The ten-line caption below the tomb illustration reads:

“Take hede un to my fygure here abowne [above]
And se how sumtyme I was fresche and gay
Now turned to wormes mete and corrupcoun
Bot fowle erth and styntyng slyme and clay
Attende therfore to this disputacioun written here
And writte it wisely in thi hert fre
At that sum wisdom thou may lere [learn]
To se what thou art and here after sal be
When thou leste wenest [expect]: *venit mors te
superare* [“death comes to conquer you”]
When thi grafe greves [grave awaits]: *bonum est
mortis meditari* [“it is good to think on death”]”

In the style of other debate poems, the *Disputacioun* then proceeds with a dream vision by the poet, who in this case has fallen asleep next to a lady’s tomb in a church along his pilgrimage route. Significantly, the pilgrim-poet informs us that he was moved to make his pilgrimage “In the ceson of huge mortalite/Of sondre disseses with the pestilence.” What follows is a rather bizarre debate between the lady’s corpse and the worms that

crawl through it, complete with marginal illustrations of a skeleton in female headdress conversing with the wriggling worms below. The corpse must accept that the worms will continue to devour her once-beautiful body, as worms have conquered all the great men and women of the past. However, by the end of the poem the body reconciles with the worms on the grounds that at the Resurrection its flesh will be restored and remade whole out of its present corruption:

“This that I hafe complemed and sayd
In no displesyng take it yow unto.
Lat us be frendes at this sodayn brayde [outburst],
Neghbours and luf as before we gan do.
Let us kys and dwell to gedyr evermore,
To that God wil that I sal agayn upryse
At the day of dome [Last Judgement] before the
Hye Justyse,
With the body glorified to be.
And of that nowmbyr that I may be one
To cum to that blis of heven in fee [by right]
Thorow the mene [intervention] and the mediacione
Of our blissed Lord our verry patrone.
Thar in abilitie [good condition] to be for His hye
plesauce.
Amen, amen pour charite at this instance.”

The Dance of Death lends itself artistically to the experience of the Black Death for a number of reasons. As the great leveler, Death comes for all regardless of their position in the social hierarchy, just as plague made no distinctions in its onslaught on Europe’s population. Typically, expressions of the dance in painting or poetry, such as the fresco that once adorned the cemetery of Les Innocents in Paris, dated to 1425, or the poem by John Lydgate, who claimed to be transcribing verses from Les Innocents during the 1430s, portray a whole descending order of victims who must dance with Death, from pope and emperor on down to hermit and poor man. But in other versions of the dance Death is a chess player, which seems to express the arbi-

trary and unpredictable nature of the plague’s geographical behavior that was recorded by some chroniclers. In addition, a dancing Death, though frightening, is more approachable and familiar than the awesome figure of the Fourth Rider of the Apocalypse. Here, at least, a mortal can communicate with Death before being taken away. Perhaps the most elaborate expression of this theme is the late medieval English morality play *Everyman*. Even though Death appears at the beginning of the play to claim Everyman and lead him to his “reckoning,” Death eventually grants Everyman a stay of execution in order to prepare his soul for the afterlife. The most revealing commentary comes at the very end of the play in a monologue by Doctor, who points

to the coming resurrection at the Last Judgement, when “we may live body and soul together.” The implied message here is that even a body rent by plague boils and other deformities will be fully restored at the end of time.

The transi tomb, a term derived from the Latin word *transire*, meaning “to pass away,” provided a variation on tomb monuments by substituting or contrasting a skeletal and rotting cadaver beneath to the idealized lifelike portrait of the patron above. Such tombs had their heyday in the fifteenth century, but they persisted as late as the seventeenth century. Nearly 200 examples survive from Northern Europe, particularly in France and England.

An intriguing feature that occurs on many of the transi tombs is a reference to or depiction of worms. For example, the tomb of François de la Sarra at La Sarraz, Switzerland, one of the earliest transi tombs constructed, in the 1390s, depicts worms on the arms and legs of its patron. As a sign of corruption and decay, worms were closely associated with the Black Death. Several physicians attributed plague to a “generation of worms” inside the body and prescribed dietary and other preservatives against worms. Likewise, the double-decker tomb of Henry Chichele, archbishop of Canterbury, at Canterbury Cathedral references worms in its epitaph of circa 1425: “I was a pauper born, then to this primate raised/Now I am lain in the ground, ready to be food for worms.” Usually, modern observers “read” downwards on this tomb, seeing the cadaver as the gruesome end product of decay of the resplendent lifelike effigy from above. But reading upward, one can also see the upper effigy as rising in resurrected glory out of the ashes of the corpse below, accompanied by a host of heavenly angels, some of which are depicted on Chichele’s pillow as well as on the canopy above.

The Dance of Death and transi tombs and other art forms representing death or mortality often have been invoked to symbolize the waning of late medieval society and culture, which supposedly had become obsessed with death. Scholars either dismiss late medieval memento mori art as, in the words of the Dutch historian Johan Huizinga, “the too much accentuated and too vivid representation of Death hideous and

threatening” or characterize the art and literature of the period as “pervaded by a profound pessimism and sometimes a renunciation of life.” There is, however, an alternative interpretation of memento mori, one that sees it as a positive, even uplifting, response to the morbid atmosphere created by the Black Death. This interpretation is closely related to medieval beliefs concerning the Apocalypse, the final destruction of the world and the salvation of the righteous as prophesied in the book of Revelation in the New Testament. Yes, medieval minds imagined the end of the world as a time of great suffering, terror, and death. But at the same time, the end of the world also holds out the promise of rebirth, renewal, and resurrection. Although it does not deny the terrible evils that plague could bring in its wake, this outlook could provide great comfort and reassurance in the face of mass death.

What Was the Population of the Caribbean and Mesoamerica before 1492?

Demographic researchers estimate that the Americas had anywhere from 8.4 million to more than 100 million indigenous inhabitants prior to European contact in 1492. To reach these approximations, scholars have used a myriad of techniques, including documentary evidence, projection models, and archaeological and ecological studies.

Demographic scholars start with an analysis of the available documentary data on aboriginal populations, which include European chronicle accounts of the number and size of native communities, baptismal and mortality records, and partial censuses taken for the purpose of tribute collection or labor drafts. Researchers supplement such limited and flawed documentary evidence with the use of projection models that estimate regional populations; total population counts based on numbers of tributaries, warriors, heads of households, or adult men; calculations of total populations based on known age groups and genders; and population estimates derived from quotas of tributary goods per family. Depopulation ratios based on population counts at earlier and later points in time also are used to approximate native populations. At the same time, scholars apply archeological and ecological studies of settlement remains, cultivation patterns, the production of foodstuffs, and environmental circumstances to enhance their research. It should be emphasized, however, that since documentary evidence, projection models, and archeological and ecological studies are imprecise, demographic researchers are not able to accurately determine pre-Conquest populations.

Estimates of the indigenous population of the Caribbean range widely from 200,000 to over 8 million people, but more current approximations limit the number to less than 1 million. Historical demographers have concentrated their debate primarily on the island of Hispaniola, the first Spanish colony in the Americas. On the higher end, Sherburne F. Cook and Woodrow Borah argue that Hispaniola had a pre-Conquest population of 8 million inhabitants based on an enumeration of tributaries that was possibly made in 1496. On the lower end, Ángel Rosenblat contends that Hispaniola possessed a native contact population of 100,000 to 120,000. He derives this estimate from Friar Bartolomé de las Casas's statement of there being 60,000 persons in 1508, taking into account indigenous population decline following European contact. For Cuba, aboriginal population estimates also fluctuate broadly between 16,000 and 600,000, but recent studies limit the number of indigenous peoples on the eve of Spanish contact to 112,000.

➤ THE GREAT POPULATION DEBATE

At its most extreme, the debate on the number of indigenous peoples living in the Americas, especially in areas colonized by the Spaniards, on the eve of European conquest has divided demographic scholars into two opposite camps: those who support low population estimates and those who adhere to high approximations. Supporters of the lower estimates argue against depending heavily on defective documentary evidence to make extrapolations. Moreover, they reject the possibility of unrecorded epidemics of European diseases, which some scholars use to calculate large contact populations and elevated depopulation ratios. At the same time, proponents of higher estimates criticize those who furnish lower figures as being too skeptical of documentary data and not giving enough credence to the various causes of indigenous demographic decline, including epidemics, armed conflicts, and socioeconomic dislocation following conquest.

It has been suggested that some who support higher estimates promote, for ideological reasons, the basic veracity of the Black Legend, a propaganda charge espoused by sixteenth- and seventeenth-century European rivals of Spain, especially the English, that denounced Spaniards as brutal colonizers who massacred millions of indigenous peoples. As a supporter of higher estimates, however, Woodrow Borah contends that other European imperialists were just as harmful to indigenous populations as their Spanish counterparts.

—Vanessa M. Ziegler

Of all the regions of the Western Hemisphere, documentary evidence on which to base population estimates are most plentiful for central Mexico. Cook and Borah employed fragmentary tributary data as well as European chronicles. Estimating that each indigenous family had an average of 4.5 individuals, they placed the population of central Mexico at 25.2 million inhabitants before the arrival of Spanish conquistador Hernán Cortés in 1519. Some researchers, however, do not agree with Cook and Borah's methodology and accept demographic calculations of 10 million to 15 million for the region instead. Additionally, the population of the Aztec capital of Tenochtitlan has been assessed at 150,000 to

200,000 inhabitants. South of central Mexico, the Maya population of Yucatán has been estimated at 800,000 people for the year 1528.

Demographic historians have found the indigenous population of Central America difficult to gauge due to the scarce documentary data available for research. Contact population estimates range from 2.25 million to 5 million indigenous peoples for the entire region.

The Population of South America

The estimated size of the native population of South America prior to the Spanish and Portuguese conquest ranges widely from 4 million to 39 million inhabitants. For South America, demographic research has converged on the central Andes (Peru, Bolivia, and Ecuador) since it constituted the Inca empire and held the greatest concentration of indigenous peoples in South America. Based on limited documentary evidence

and the use of depopulation ratios, approximations for the central Andes vary broadly from 3 million to 30 million inhabitants. For Peru, Noble David Cook estimates an original population in the year 1520 of 9 million inhabitants. Research on Bolivia has resulted in a partial population estimate of 743,000 inhabitants, while the total contact population for Ecuador ranges from 500,000 to 1 million people.

Demographic calculations have been made for other parts of the Andean region as well. The Venezuelan population has been estimated at 350,000 inhabitants, and Colombia's contact population has been calculated as high as 3 million.

The southern region of South America had a small indigenous population prior to the Spanish conquest. Based on documentary evidence, projections of the contact population of Argentina vary from 300,000 to 981,500 inhabitants. For Chile, aboriginal population estimates range from 500,000 to 1.5 million prior to European contact. Finally, the Uruguayan and Paraguayan precontact populations have been calculated at 5,000 and 280,000 native inhabitants, respectively.

Amazonia encompasses the area surrounding the Amazon River and its offshoots as well as the tropical zones of the South American interior. William M. Denevan offers an estimate of over 8 million indigenous people for all of Amazonia based on documentary data, depopulation rates, and the ecological patterns of different habitats in the region.

The calculation of the Brazilian aboriginal population has fluctuated from under 1 million to 3 million people. John Hemming provides perhaps the most accurate estimate based on firsthand European sources, an assessment of the land arability in each region, and the consideration of indigenous depopulation as a result of the proliferation of diseases stemming from European contact, social dislocation, and slavery. For the year 1500, Hemming estimates that there were approximately 2.4 million indigenous people living in Brazil.

The Population North of the Rio Grande

The histories of Native American populations north of the Rio Grande before 1500 are diverse and idiosyncratic. Encompassing all of present-day Canada and the United States, each specific cultural region within this area had its own unique demographic history and population dynamics. In some areas the natural environment and resources allowed for large populations to develop and reside over long periods of time, while in other areas the environment and resources precluded the local population from ever growing beyond a few hundred or thousand.

For example, archaeologists have estimated that between 10,000 and 20,000 families populated the Four Corners area of the Southwest region 800 years before the present. However, within a short time period, roughly 150 years, these large population groups had moved to other areas of the Southwest. During the mid-eleventh century most of the great houses in the area were vacated, and by the late twelfth century most of the remaining great houses and smaller villages experienced large-scale population decline.

Slightly earlier and to the north in the eastern Great Basin of present-day Utah, Native American populations archaeologically classified as Fremont also experienced large demographic fluctuations. Archaeological evidence, for exam-

➤ OUR EVIDENCE FOR NATIVE AMERICAN POPULATIONS

Evidence for understanding Native American populations north of the Rio Grande before 1500 stems primarily from archaeological and physical anthropological data. Archaeological evidence includes prehistoric village size and building uses, shell and refuse midden sizes, site and regional densities, and the overall occupation chronology of both the site and the region. When studied together, these data allow archaeologists to estimate the total number of individuals living within a particular area over a set period of time. Physical anthropological data include osteological evidence (evidence garnered from the study of bones), our knowledge of human adaptive responses to environmental and population stresses, and estimates of population birth rates, infant mortality rates, and general mortality rates. Taken together, these two forms of data—archaeological and anthropological—allow researchers to develop a fairly rigorous understanding of a site’s occupational chronology and the larger region’s demographic history.

—Peter N. Jones

ple, indicates that relatively large populations lived in the northern part of the greater Uinta Basin of northwestern Utah between 640 and 1000 CE and that these populations then rapidly declined. At the same time, populations grew in the southern part of the basin between 1000 and 1150. By 1200, however, the entire basin was rapidly depopulated, as the local climate changed and people had to look elsewhere for sufficient resources.

In California, however, where subsistence regimes were oriented more toward the coast and riverine resources, the population demographics remained more stable overall, although some areas, such as San Francisco Bay, apparently experienced some redistribution of populations, as evidenced by shell mound locations.

In the Mississippi region to the east, a similar pattern of fluctuating demographic history is also evident. Cahokia, one of three Mississippian archaeological sites that made up a part of a large political-administrative complex in the middle Mississippi River Valley, is estimated to have

grown from around 10,200 people to 15,300 people between 1050 and 1100. It has been estimated that at the same time the regional population swelled to between 30,000 and 50,000 people. A similar demographic evolution also took place on the eastern coast of the United States as chiefdoms expanded, contracted, and migrated across the landscape. In other regions such as the Plains, Subarctic, and Arctic, lack of subsistence resources precluded the prehistoric peoples from reaching beyond a few thousand.

The Peoples of the Pacific—Environment and Population

Melanesia was first occupied by modern humans tens of thousands of years ago, while Micronesia and Polynesia, among the last places on Earth to be peopled, were first occupied only thousands of years ago. By 1000 CE more than a million people lived scattered across Oceania's diverse land masses. On the basis of their study of archaeology, ecology, linguistics, oral histories, and estimates by early Europeans, demographers such as John Caldwell of the Australian National University have been able to arrive at rough approximations of population numbers for the various societies of Oceania.

Much of Melanesia, including New Guinea, and New Zealand in Polynesia are continental land masses with a diversity of plants and animals. Many of the smaller land masses, such as Fiji and Hawaii, are high islands formed by a combination of volcanic activity and coral buildup. These are less biologically diverse than the continental land masses. The low islands of the Pacific, including most of Micronesia, are coral

atolls only a few feet above sea level. Low islands are less biologically diverse than either the continental land masses or the high islands.

Almost every type of climate zone known on the planet can be found in Oceania. Even though most of Oceania is within the tropics, variations in altitude result in a variety of ecological niches. Environments throughout the region range from seacoasts to mangrove forests, swamps, rainforests, cloud forests, alpine forests and meadows, semitropical coniferous forests, and semitropical deciduous forests.

Tens of thousands of years ago, during times when the sea level was lower than it is now, the first modern humans migrated out of an area that now includes Indonesia and into Melanesia and Australia. In 1000 CE the population of Melanesia was about 564,000. By 1500 CE it had increased to about 718,000. Evidence of the great length of time that modern humans have lived in Melanesia is reflected in the diversity of languages spoken there. In New Guinea alone about 1,300 languages, maybe a fourth of the world's total, were spoken. Most of these languages are classified as Papuan. With diffusion and migrations into Melanesia from Micronesia and Polynesia, Austronesian languages appeared at later dates.

Austronesian languages probably have their origins in southern China and Taiwan. From those points Austronesian became one of the most widespread language groups on the planet. The seafaring skills of Austronesians spread their languages to the nearby Philippines; south into Island Southeast Asia; west as far as Madagascar, 250 miles (400 kilometers) off the east coast of Africa; and east as far as Easter Island, 2,300 miles (3,700 kilometers) off the west coast of South America. The distance between these extreme east-west points of settlement is 210 degrees of latitude, or 58 percent of the circumference of Earth.

Micronesia was settled in more than one migration with the earliest influx of modern humans into Micronesia about 6,000 years ago. The earlier group of migrations probably started in the Philippines, Taiwan, the Indo-Malaysian archipelago, and/or parts of Melanesia and ended up in the western part of Micronesia. The central and eastern parts of Micronesia were settled

in later migrations, probably from Melanesia to the south but also maybe from western Micronesia. In 1000 CE the population of Micronesia was about 86,000, but by 1500 CE it stood at about 137,000.

Polynesians are probably the descendents of Austronesian-speaking peoples from Indonesia or the Philippines who pushed into northern Melanesia and then about 3,000 years ago into the Samoa-Tonga-Fiji region of western Polynesia. It is on Samoa and Tonga that typically Polynesian culture developed and spread eastward to the Marquesas and then to other areas of eastern Polynesia. The last area of Polynesia, Aotearoa (New Zealand), was settled only about 1,000 years ago. As populations reached their carrying capacity on particular islands, groups of seafarers set out in search of new lands, ultimately populating all of Oceania. Searching for new lands may have been an incentive to lower-ranking individuals of chiefly families who could establish new societies in which they were the highest ranked. In 1000 CE the population of Polynesia stood at about 78,000. By 1500 CE it had increased to about 160,000.

➤ DEBATE OVER THE POPULATION OF EASTER ISLAND

Until recently archaeologists have generally agreed that Easter Island was first settled around 350 CE by 50 to 200 people from elsewhere in Polynesia. By 1500 CE the population of Easter Island had reached its maximum carrying capacity of about 8,000 people. Yet the population continued to grow, maybe to 20,000 people. At that time the expanding population resulted in food shortages, deforestation as more land was cleared for farming, soil depletion, intergroup conflict, and religious upheavals. The shortage of timber meant a halt in boat-building that would have allowed people to exploit tuna and other offshore fish. When Europeans arrived in the eighteenth century, the population of Easter Island may have dropped to 3,000 people.

New radiocarbon dating on Easter Island has suggested to some archeologists that Polynesian settlers first arrived much later. Terry Hunt and Carl Lipo argue that if the first Polynesians arrived in 1200 CE, there would not have been time for overpopulation to occur. A population of about 3,000 at the time of European discovery may have been the maximum the island ever supported. Rather than attribute the demise of Easter Island society to natives' destruction of the environment, Hunt and Lipo blame rats and Europeans. The Polynesian rat, an uninvited passenger on the canoes of the first settlers, may have destroyed much of the island's food. Europeans then introduced new diseases and began slave raids that destroyed the culture.

While Hunt and Lipo's theory is intriguing, until more evidence in support of their explanation comes to light, most archaeologists continue to advocate the older interpretation.

—*Sharlottte Neely*

■ Introduction: Envisioning the Environment

Nature can be forbidding, even terrifying, and its ways are mysterious for those who have no means of explaining, adapting to, and even protecting themselves from its rhythms. For that reason, human societies since

the beginning of the species have attempted to make the world of nature a comprehensible and comfortable place in which to live through their myths, legends, visual arts, and, if sufficiently literate, their literature.

The entries contained under this topic illustrate only a few of the many ways that both settled and nomadic as well as literate and illiterate cultures envisioned and represented the natural environment in which they lived during this half millennium. Cumulatively, these entries can only give us a glimpse, and a partial one at that, of the global varieties of this phenomenon.

Most historians, unlike social scientists, are reticent to search for and to proclaim general rules and patterns supposedly at work in human history. They are too mindful of social and cultural differences and the roles that chance and accident play in the unfolding of the human story. Yet more so than most of their colleagues who practice the discipline of history, world historians are, very much like anthropologists, open to perceiving commonalities, as well as differences, within the human experience. One such commonality that seems evident to those who study the visual and literary arts is that as societies become more settled and stable, one might even say more mature, their visual artists and writers tend to portray nature as less hostile and more benign and even inviting. That certainly appears to have been the case for many societies around the world between the years 1000 and 1500.

The folk tales of dark and dangerous forests filled with menacing creatures tended to give way in twelfth- and thirteenth-century Western Europe to edifying tales of nature tamed, as seen in the popular story of Saint Francis of Assisi's converting "Brother Lupo," the wild wolf of Gubbio, to a life of peaceful coexistence with the citizens of this Italian town. This same saint, the author of the *Canticle of the Creatures*, also was portrayed, in a fresco mural painted by Giotto and his students in the church of San Francesco in Assisi, preaching the love of God to birds.

Although Francis and Western Europe's so-called Twelfth-Century Renaissance are represented in these pages, unfortunately China's Song-era paintings of nature have not yet found an author or a voice here. This is unfortunate, because the greatest artistic glory of Song China (960–1279) was its landscape painting. In fact, nature and landscape were not mere background for Song painters; they were the focus. Song China raised landscape painting to a pinnacle

that few cultures have equaled and none have surpassed in beauty, sophistication, and philosophical complexity. Underlying this art was a uniquely Chinese combination of philosophical and religious traditions. Daoists extolled the awe-inspiring mystery of nature and underscored the insignificance of the human imprint on the vast all-encompassing cosmos. Neo-Confucianists asserted that there exists an infinite Moral Principle (*li*) that pervades, harmonizes, and energizes the universe and all that is contained within it. On their part, Buddhists emphasized the need for a harmonious interaction between humanity and nature, whereas traditional folk religion, which greatly influenced Chinese Buddhist devotion, held that mountains were sacred spaces where the immortals dwelled. Proceeding from such roots, Song artists portrayed a natural world that was harmonious yet complex, ordered yet mysterious, inviting yet awe-inspiring. Nature so portrayed became both an entity unto itself, to be appreciated for its intrinsic beauty, and a metaphor for a well-ordered empire within an orderly universe.

Indeed, a desire to portray a perceived order in nature was common to all of the artistic and literary traditions reflected in these entries, be they artists incising animals on stones, gardeners fashioning and caring for the taifa gardens of Al-Andalus, or Mesoamerican and Incan urban planners replicating sacred space in the built environment of their cities.

—Alfred J. Andrea

Sub-Saharan Art of Nature

Scholars have noted that the unique qualities of sub-Saharan African art were inspired and necessitated by an understanding of animals in the savanna (grasslands) and the forest. According to this theory, African art is typified by two fundamental tenets that have guided the artists in their art production. The first is a strong feeling for the attributes of animals as they affect humans and the environment. The second is the idea that humanity is essentially a creation of nature. In African masks and artistic representation of animals, we see continuity in motifs and forms from the art of the people who occupied the central Sahara 8,000 years ago to the art of

the people in the grasslands of Central and South Africa transmitted down to today.

Africa south of the Sahara has been home to communities that lived in accordance with the environment and the seasons. Moreover, these peoples farmed and hunted, and consequently they were principal actors in societies in which knowledge of the behavior of animals was of paramount importance. Many myths were built around these animals, and the peoples' social systems and religious beliefs were affected by their knowledge and interpretation of the appearances and behaviors of these animals.

In many societies as widely spread as the Buganda in Uganda to the Basotho in southern Africa, animals were recognizable as characterizing certain types of people by well-known artistic conventions. The symbolic representation of animals and their attributes was not restricted to any particular tribe or location. For example, the bush cow of the Poro on the Ivory Coast, with its threatening sound, can also be found represented in the art of Malawi. The python usually associated with the Fon throne of Bamun was also a powerful symbol in Swaziland. And the Chameleon of the Chief sitting on the bush cow horns in Nigeria was a motif of equal importance among the Bayaka of the Congo.

Several centuries before 1000 CE, the Igbo-Ukwu culture of eastern Nigeria made artifacts in bronze iron and terra-cotta that reflected their environment. Insects, shells, and animals were characteristic Igbo Ukwu forms and decoration. Between 1000 and 1500 CE (according to radiocarbon-14 dating), the Ife, or Yoruba, artists of southwestern Nigeria made stone sculptures in the form of mud fish and animals.

The Tellem people of Mali built granaries between the eleventh and fifteenth centuries CE. Strong evidence abounds that the granaries served both as food storage areas and as burial vaults. Caves were also used as burial vaults. Significantly, grave gifts have been found in these burial chambers that reflect the occupations and status of the deceased. Farmers are recognized by the hoes buried with them, and hunters are recognized by their bows and arrows and the skulls of game animals. The Dogon people, who arrived later and occupied the land when the Tellem people left, invariably maintained a simi-

➤ THE SIGNIFICANCE OF THE LEOPARD IN BENIN ART

Bronze plaque decorated with two leopards, from Benin City, Nigeria, possibly late seventeenth century. Such plaques adorned the walls of the palace of the obas (divine kings) of Benin. (Werner Forman/Art Resource, NY)

Images of various creatures were explored in the art of Benin that dates from circa 1400 CE. The forms were executed in three media: bronze, wood, and ivory. Creatures such as leopards, pythons, horses, frogs, lizards, and birds were used as symbolic motifs. The leopard in particular was ascribed such human attributes as leadership, authority, and courage. The animal was associated with royalty and was elaborately used in the art of Benin's royal court.

—Tolulope Lawrence Akinbogun

lar culture. The Dogon believe in a supreme creative force, Amma, who resides in the skies. Thus, their art, consisting of wood carvings, was fashioned in a manner that was consistent with their religious and philosophical beliefs as well as their concept of cosmology. The Dogon cosmology holds a mythological position that Amma created the earth and had a sexual relationship with it. Through the earth, Amma procreated and had fox (*Vulpes pallida*) as its first child. The earth bore a set of twins for Amma during the second birth. The twins were called Nommo. They were human beings from head to waist and serpentlike below the waist. These mythological beings were often depicted in Dogon carvings.

Japanese Reverence for the Natural World

The Japanese reverence for the natural world is anchored in the tradition of an animistic worldview that favors the idea that all things in nature (i.e., animals, plants, formations of landscapes such as mountains, lakes, or rivers) are spirited. The term for nature is *shizen* in Japanese, and the literal meaning of the Chinese character with which this word is written is “from itself thus it is.”

Humans are considered an integral part of nature, as are spirits. Consequently, respecting the natural environment is part of humanity's protection of its own living space. The Japanese do not perceive nature as a realm to be dominated. Shaped by a long tradition of animism, proper social conduct includes communing with

the spirits of nature as a symbolic act to further the sustainability of community life. This communion with the spirits requires the observance of offering ceremonies and regular visits to temples.

Perceptions of a spirited world are widespread among the indigenous populations in Northern Eurasia and North America. Japan—located on the eastern rim of Eurasia—forms part of this cultural convergence and, as an ancient cultural layer, has perpetuated animistic ways of looking at the natural environment up to the present. The animistic worldview of the Japanese people is called Shintoism, a derivation from Shinto (spirits; divine beings), a fairly modern term modeled on such equally vague and overly general terms as “Buddhism” or “Hinduism.” In Western descriptions of Japan, Shintoism is often identified as a religion. In fact, Shintoism is a way of life.

The central spiritual category of Shintoism is *kami*. The same Chinese character is used to write the two expressions *kami* (an indigenous Japanese term) and *shin* (a Sino-Japanese term, with a reading according to the Chinese tradition). *Kami* and *shin* refer to the spirit that resides in every object and/or place. For instance, Mount Fuji (Fujiyama) is no mere landmark in a wider landscape; it is a sacred spirited space, a place of pilgrimage, where the Japanese have let themselves be impressed by the experience of watching the sun rising over the mountain's top and where the feel for Japanese identity readily crystallizes.

The respect for nonhuman life forms is similar in Shintoism and Buddhism. Therefore, Buddhist thought is much less alien to the Japanese mind than Christian monotheism. Buddhism, a religious import from Korea and China that infiltrated the islands beginning in the sixth century CE, spread easily in Japan, and it engaged in a dynamic interaction with the older worldview to create patterns of a symbiotic coexistence in the lives of Japanese people. Both Shintoist and Buddhist ceremonies may be attended by the same person.

According to H. Byron Earhart, among the Japanese people the basic principles of respect for nature “are more readily experienced as directly perceived sentiments than as logically dem-

► THE SUN IN JAPANESE TRADITION AND POPULAR THOUGHT

The sun was not chosen as the central motif in the modern national flag of Japan in 1870 because of the concept of Japan being the “land of the rising sun,” as is popularized in Western lore. Rather, as the supreme *kami*, the sun is a central mythical symbol. In Japanese mythology and popular thinking, this celestial body is a goddess, named Amaterasu (Heavenly Shining One).

Mythological tradition has it that Amaterasu founded the Japanese nation by sending her grandson Prince Ninigi down from the Plains of Heaven to govern the islands. Consequently, Amaterasu's grandson was the founder of an unbroken lineage of Japanese emperors.

—Harald Haarmann

onstrated propositions.” Japanese art, literature, and folklore have been infused with the effort to establish a balanced relationship between the living space of human beings and nature. Manifestations of this traditional mind-set are first documented during medieval times. In Murasaki Shikibu’s early-eleventh-century classic *Tale of Genji*, the rhythm of nature in its seasonal cycles is a major thematic element. Likewise, the painting of nature, of beautiful landscapes, of birds and flowers, became popular during the fourteenth century.

Animal Effigies in the Art of Inner Asia

A common theme in Inner Asian art revolves around animals. Considering the importance of animals in the lives of pastoral nomads, this is not surprising. Horses, camels, sheep, goats, and cows or yaks are central to the lives of all nomads. In addition, other animals appear frequently in Inner Asian art, with horses, wolves, and deer being the most common. Animal effigies carry not only artistic importance in Inner Asian culture but also significant symbolic importance. The animal may be the totem animal of a tribe, such as a wolf for many Turkic tribes. These effigies often appear as animal shapes cut from leather or felt and then sewn onto clothing or the tent known as a *ger* (Mongolian) or *yurt* (Turkic).

The animals also appear quite frequently as petroglyphs (rock carvings) throughout Inner Asia. Among the most famous are deer stones that appear in virtually all eras but that first originated in the Neolithic period. They were then refined by the Tagar culture of Siberia (eighth

These petroglyphs depicting deer were carved well before 1500. The first, in present-day Kazakhstan in the western steppes, shows the typical stylized deer of Inner Asia with backward-flowing antlers. The second, in the present-day province of Inner Mongolia, China, depicts a less stylized deer and what appears to be a ground rodent with an exaggerated tail. (Alfred J. Andrea)

through second centuries BCE) and the roughly contemporaneous Scythian culture of the western steppes. Rather than being carved into cliff walls, deer stones usually appeared in slabs that were then inserted upright into the ground and served as menhirs, or obelisks. These are notable insofar as the Scythians and later artists adopted a common form, with the antlers of the deer flowing backward for almost the entire length of the deer’s body, and the deer is often described as flying. Over time, the deer stone model of a deer transitioned into other art forms, such as finely crafted bronze and gold jewelry and appliqué. Although archaeologists have speculated on the meaning of the deer stones, their exact purpose and meaning remain unclear. Nonetheless, they appear to have been associated with the shamanistic worship of a deer goddess, who was the source of life and death in the steppe.

Animal effigies carried great significance among shamans. Often their staves had an animal head carved into them, typically a horse. As the shaman traveled in the spirit world the staff was his mount, in a fashion similar to the European concept of witches on broomsticks. The staff housed the shaman’s spirit helper; hence, a horse-headed staff transformed into a horse. Other spirit helpers also took the form of animals

that might be included in the gear of a shaman such as hawks, owls, foxes, wolves, and elk. Often the shaman's drumstick also bore an animal's head. This has carried over somewhat into the modern period in Mongolia. The *morin buur*, alternatively known as the horsey-fiddle or horse-headed fiddle, is the national musical instrument of Mongolia. As the name implies, the top of the neck of the instrument has an ornately carved horse's head.

Animal effigies also served a totemic purpose. The early Turkic empires identified with the wolf and often carried banners with a wolf or wolf head on it, as they considered themselves descended from a she-wolf. Other legends have the wolf leading them to new lands or aiding them when in peril, and wolves adorned belts and garments. The banners of Chinggis Khan carried the emblem of a falcon, the symbol of the Borjigin clan whose originator survived his early days by hunting geese with the aid of a falcon he caught and trained to hunt.

The Taifa Gardens of Al-Andalus

Garden design and construction during the Taifa period (1031–1091 CE) owe much to the legacy of its Andalusian predecessor, the Caliphate of Córdoba, and its greatest palace-city, Madina al-Zahra (see Era 4). Despite the collapse of unified rule in Al-Andalus by 1031, the cultural and architectural legacy of not only the Spanish Umayyad court but also its Syrian Umayyad predecessors was assured, and these styles would

be consciously reproduced in both the palaces and gardens built throughout Islamic Spain during the Taifa period. In addition, such forms and designs would later be incorporated into the models and themes found in both Muslim and Christian contexts throughout medieval and early modern Spain.

Gardens in Al-Andalus were not public spaces but instead were private places intended for the use and pleasure of the owner, whether khalifa (caliph), emir (prince), nobleman, or merchant. One type of garden was found within the walled spaces of palace residences and contained a variety of ornamental trees and exotic flowers. A common design found in these gardens was a layout with an open roof and a cross-axis below where the available space was divided into four equal parts, creating elevated walkways, and sunken beds of plants filled each section. A basin or fountain could often be found in the center of the axis, and channels or pools of water ran along the outer edges of the garden.

Many such residences were built adjacent to or just outside the city walls and often included larger surrounding garden spaces intended for agriculture. Orchards with fruit or olive trees and vineyards were often located in this type of garden and were watered with irrigation techniques developed in the Middle East and brought to the arid environment of Al-Andalus. These residences were often built with terraces or a raised vantage point, called a mirador, allowing the viewer to enjoy panoramic vistas of the landscape and countryside outside the confines of the residence.

Whether intended for ornamental or agricultural use, gardens throughout the medieval Islamic period in Al-Andalus were designed with a sense of order and harmony between the buildings and the land and were an early expression of what is known today as landscape architecture.

► THE ALJAFERÍA

A famous taifa residence is in Zaragoza, where Abu Jafar al-Muqtadir (1046–1082) built a walled palace complex, the Aljafería. Al-Muqtadir was a poet, mathematician, and astronomer, and his court attracted writers and intellectuals from all over Al-Andalus.

The garden at the Aljafería was the interior style and today is known as the Patio of Santa Isabel. Rectangular-shaped with an open roof, it included reflecting pools and ornamental plants. The garden was the backdrop for al-Muqtadir's court, famous for its poetry recitations and musical performances.

Little of the current site is original, the complex having undergone many renovations. Long after the Christian conquest of the city in 1118, the site was used to house the Spanish Inquisition. Today it is the headquarters of the provincial government of the province of Aragón.

Changing Perceptions of the Natural World—Europe, 1000–1400

During the period circa 1000–1300, Western Europeans entered into a dynamic relationship with nature that is exemplified by a revolution in the arts. Indeed, European artists drew upon various traditions and stimuli to create an art that was increasingly vibrant and naturalistic, especially from the late twelfth century and onward. This dynamism can be traced in part to a renewed interest in Roman statuary and classical Latin literature, as well as to a new emphasis on human emotions, including physical love, as expressed in Europe's emerging vernacular literatures. These and so many other strands, such as Europe's new general prosperity and relative stability, coalesced to create a multiplicity of expressions that proclaimed the intrinsic beauty and worth of all creation. One of the most important was an increasing emphasis on the humanity of Christ, which became central to this artistic revolution and the naturalism that was an integral part of it.

An early example of this emphasis on the humanity that all persons share with Jesus is the

➤ EXCERPT FROM FRANCIS OF ASSISI'S CANTICLE OF THE CREATURES

“All praise be yours, my Lord, through all that you have made,
And first my lord Brother Sun,
Who brings the day, and light you give to us through him.
How beautiful is he, how radiant in all his splendor!
Of you, Most High, he bears the likeness.
All praise be yours, my Lord, through Sister Moon and Stars;
In the heavens you have made them, bright and precious and fair.
All praise be yours, my Lord, through Brothers Wind and Air,
And fair and stormy, all the weather’s moods,
By which you cherish all that you have made.
All praise be yours, my Lord, through Sister Water,
So useful, lowly, precious and pure . . .
All praise be yours, my Lord, through Sister Earth, our mother,
Who feeds us in her sovereignty and produces Various fruits with colored flowers and herbs.”

“The Canticle of the Creatures,” in Benan Fahy, O.F.M., trans., *The Writings of Saint Francis of Assisi* (Chicago: Franciscan Herald Press, 1963), 130–131.

Gero Crucifix, which was crafted in the Rhineland around the year 1000. It depicts Christ hanging on the cross, apparently just moments after his death. The image is moving, even unsettling, in its frankness, but that graphic depiction of the God-man’s suffering and death lends dignity to the natural state of all mortals. Indeed, the realism of this crucifix foreshadows much of the naturalism that was to follow.

That naturalism was taken to new levels by the sculptors who worked on the great twelfth- and thirteenth-century Romanesque and Gothic cathedrals that are found throughout Western Europe from England to Italy. Indeed, many of those cathedrals, particularly Chartres in northern France, became centers of language, learning, and art.

The sculptural art at Chartres is stunning in its scale and vibrancy. The West Portal (ca. 1225–1245), for example, is austere yet inviting, evocative of the ancient Roman world’s artistic realism, but combined with the Latin Church’s emphasis on the human Christ, the brother of all persons. A person walking through the portal is greeted by an image of the risen Christ on a throne, inviting visitors to enter into the church’s sanctuary. Beyond this obvious religious symbolism, Chartres cathedral was home to a school that emphasized study and emulation of the thought and literature of the classical Roman world but blended with the Christian tradition. Interestingly, some of the masters of Chartres were avid students of nature. Some modern scholars have suggested that the twelfth-century writers, philosophers, and artists produced by such cathedral schools as Chartres were precursors to the Renaissance that developed later in Italy. If so, and it appears to have been the case, then twelfth-century Latin Christendom was a chief foundation stone upon which the later Renaissance in Italy was built. But it was not alone in this role.

Just as Byzantine scholars played a role in the later Italian Renaissance, Byzantine art played a complementary role to this earlier European revival of antiquity’s realism. Examples abound of Byzantine-influenced art and architecture from southern Italy to France and Germany, but it is debatable whether Byzantine or Byzantine-influenced art ever reached the intense realism and naturalism that medieval Europeans produced, despite some early-fourteenth-century fresco art in Constantinople’s church of the Holy Savior in Chora that is striking in its portrayal of the human body. To illustrate this point regarding Western art, it is helpful to examine briefly the life of St. Francis of Assisi (ca. 1182–1226).

Francis’s life is symbolic of the newfound realism and naturalism that evolved in European art. He called for his followers to live simply and to respect nature as God’s creation. His *Canticle of the Creatures* exemplifies his care for nature and his devotion to God. Francis’s devotion was multidimensional. Fittingly, the Italian painter Giotto’s depictions of important moments in the saint’s life at Assisi’s Basilica of San Francesco were equally multidimensional.

In these paintings, known collectively as the *Vita Cycle* (*The Life Cycle*), the viewer is confronted with a world in which the characters live and thrive. Giotto's *St. Francis Preaching to the Birds* (ca. 1297–1299) illustrates this well. There we see the Saint interacting with and caring for birds, thus showing his followers how they ought to follow his example. There are some Byzantine influences in Giotto's frescos (as there is in a great deal of Italian art from that period), but it is clear that Giotto went beyond the stylized formality of most Byzantine art. It is equally clear that Giotto's art evolved as part of a larger European concern with nature and the recovery of antiquity's realism.

Early Renaissance Visions of the Natural World

Early Renaissance Italy (ca. 1300–1500) witnessed an explosion in artistic, literary, and architectural creativity that had not been matched in volume or scope in the West since classical antiquity. While there are certainly glimpses of similar revivals in contemporary central and northern Europe, an especially high concentration of *ingegno*, or ingenuity, in Italy's diverse communes and city-states seems to have borne the greatest artistic fruit. Florence, Venice, Rome, and Ferrara might come immediately to mind when one thinks of the Renaissance cities and courts that produced artistic brilliance, but Siena in the first years of the fourteenth century

Frontispiece to a manuscript of the works of Virgil by early Renaissance painter Simone Martini. (Scala/Art Resource, NY)

surpassed all of those pillars of culture in the stunning number of brilliant artists that it produced. Indeed, Siena, with its population of perhaps 30,000 people, made a lasting mark on the evolution of art in Renaissance Italy and eventually throughout central and northern Europe, especially France. What was so special about the Siennese school that its influence became international? It revolutionized the way in which artists portrayed humanity and particularly nature. Indeed, Siena's painter-artists brought to their mural frescos and manuscript illuminations a revolutionary realism and naturalism.

When examining Siennese artists, one is forced to consider their inspiration, the Florentine school that included such notables as Cimabue (ca. 1240–ca. 1302) and Giotto (ca. 1267–ca. 1337). The two were towering talents of the late medieval and early Renaissance period, but they

➤ PETRARCH'S CANZONIERE (SONNET), 77

(To thank Simone Martini for drawing Petrarch's beloved Laura)

"If Policlitus endeavored to gaze intently
(With the others who are famous in that art)
For 1000 years, he would not see the tiniest part
Of the beauty which has, my heart, conquered;
But certainly my Simone was in paradise
(from whence this noble lady springs),
[And] there he saw her and sketched her on paper
So that by her lovely visage faith might spread
[here on earth] below.
The work truly was of the kind that in heaven
One might be able to imagine, [but] not [down]
here among us,
Where the body is made to veil the soul.
A gracious gesture, though he could do nothing
more there
Once he had descended to test the heat and ice,
And saw as mortals do with his eyes."

Translated by William Landon

—William Landon

failed to reach the lyrical and emotional qualities of their Siennese neighbors to the south. Of the Siennese artists, one comes to the fore: Simone Martini (ca. 1280/1285–1344). Martini is of particular interest because he was certainly influenced by his fellow Siennese painters as well as by artists from Florence, but he was also influenced by the Gothic French style, which provided an element of volume and space to the characters and scenes he depicted.

Martini served Robert of Anjou, a French monarch, at the court of Naples. There, it seems, Martini became increasingly influenced by French style. However, he never allowed French gothic influences to suppress his dual Florentine and Siennese heritage. On the contrary, what made Martini unique is that he produced a blend of these divergent styles to produce a new international form of painting. Indeed, his fame at the French court at Naples could not be contained. Word of his talent traveled to the exiled papacy at Avignon, where he was called to serve as a court painter.

While in France, Martini became acquainted with Francesco Petrarch. Evidently the two became fast enough friends that Petrarch included Martini in his *Sonnets*. Evidence that the friendship was mutual can be found in a manuscript of Virgil (the *First Eclogue* and other extracts) that Martini illustrated for Petrarch. That small painting deserves further attention as it serves to illustrate how revolutionary Martini's style became. Martini's illuminated *Virgil codex* brings together various strands of the early Renaissance: revived Latin literature, Petrarch's humanism and, of course, Martini's own emerging naturalism.

Martini's brushwork in the *Virgil codex* is elegant, and the mannerisms, gestures, and posture of his figures are altogether different from those of other Italian painters of the period. One might argue that Martini's lyricism and naturalism might even surpass that of Giotto. Some historians have gone so far as to suggest that Martini's languid and beautiful brushstrokes resemble those of the nineteenth-century French impressionists Monet and Renoir. This might seem to be a strained connection, but nonetheless it gives us some idea of Martini's grasp of the movement of light, the relationship of the figures in the painting to one another and to their increasingly naturalistic environment. Perhaps, most importantly, Martini's mixture of French gothic and Siennese styles produced a magical combination that emphasizes the relationship of the viewer and the painting, a revolution in Western art.

American Indian Views on the Environment

The phrase "religion and ecology" refers to the influence of belief systems on human attitudes

and activities affecting nature. An alternative model for studying Native Americans' approach to the environment employs the concept of "lifeways," whereby the religious, ecological, and sociocultural aspects of life are aspects of a seamless whole, rather than discrete areas of activity. Traditional narrative stories for entertainment and the passing on of knowledge reveal the conflation of these categories. Characters in the stories are human and nonhuman, or combine human and animal qualities, signifying a close commonality between human and nonhuman populations. Indeed, many stories describe a time when human and nonhuman animals spoke the same language, and the stories suggest the possibility that knowledge of nonhuman languages is not completely lost. Persistent descriptions in American Indian stories of a relational model of daily life among all life, including human, is the basis for a worldview representational of an interconnected, interdependent universe, dynamically sustained by humans through an ongoing matrix of reciprocal relationships.

Although it is difficult to speak of generalities concerning the native populations throughout the Americas, it is clear that a common idea of the interdependence of all life was prevalent in the centuries preceding the Columbian Exchange, and it remains so down to today. This interdependence is created and sustained through a protocol of respect-based relationships, or reciprocal relationships. Many narrative stories of various Native American traditions describe the need for the maintenance of respectful reciprocity between humans and the nonhuman world, and many describe the negative consequences of disrespectful or unconscious actions. Briefly, the earth and larger universe are often considered as inseparable from the prime creative power responsible for bringing the world into being. The maintenance of respectful relationships helps to ensure not only the survival of those engaged in relational activities (for humans, that includes actions such as gathering food, hunting, trading, and living in community) but also the ongoing health of the world at large.

Linguists have commented on the striking lack of terminology in American Indian languages concerning "nature" as a discrete concept. Like-

wise, there is no word for religion in most Native American languages, exemplifying the integrative nature of their worldview. The activity of daily life is religion, and all actions have a sacred dimension: there are a "right" way and a "not-so-right" way of living one's life. Being in harmony with the world, with the ways of the ancestors, with society, with community, and with family is a properly lived religious life. The maintenance of a proper relationship with one's surroundings implies sustainability, rendering the creation of a secondary self-identity as an environmentalist unnecessary.

Mexica Sacred Geography

The Mexica (also known as the Aztec) empire—the last of the great Mesoamerican civilizations—dominated the highlands of central Mexico at the time of the arrival of Hernán Cortés in 1519. The Mexica empire had risen to power following a series of military conquests just a century or two earlier and maintained economic control by extracting tributes in the form of foodstuffs and raw materials (as well as personal services) from conquered populations. The Mexica capital of Tenochtitlan, situated at the center of present-day Mexico City on an island approached along three long causeways, had an estimated population of 250,000. The mass sacrifices to the Mexica war and sun god Huitzilopochtli, which took place at the great Templo Mayor in the center of the city, are legendary.

The landscape around the Mexica capital is characterized by strings of mountains and towering volcanoes that surround and dominate flat valleys, creating obvious associations among

mountains, clouds, rains, fogs, thunderstorms, springs, and rivers. Under the valley floors and mountain slopes are numerous caves created by ancient lava flows. In Mexica times, the landscape was also peppered with magnificent human constructions, both the temples of the Mexica themselves and the conspicuous remains of earlier temples dating back to the Preclassic period (at least as far as the mid-first millennium BCE). This combination created, in the Mexica mind, a vibrant perceived world strewn with the abodes of powerful spirits: mountains were sources of water and rain, caves were entrances to the underworld, and the huge ceremonial center of Teotihuacan with its enormous pyramids, 1,000 years old by this time, was itself seen as a magnificent creation of the gods.

Tributes to the gods had to be made in the appropriate place but also at the correct time. One of the most critical actions was to appease Tlaloc, the god of rain and fertility, and persuade him to send water for the year's maize crop. Petitions to Tlaloc were timed in relation to calendar festivals and often involved the sacrifice of children. Thus, on the first day of the month Atlcahualo in the 365-day calendrical cycle (*xihuitl*), or around the middle of February in the Gregorian calendar, the bodies of sacrificed children were thrown into caves close to mountain sanctuaries, since the water was thought to remain there, inside the mountain, until released by the gods as rain. On the summit of Mount Tlaloc itself, at an elevation of more than 13,000 feet (4,000 meters), was a shrine containing an idol of the rain god where the nobles from Tenochtitlan and adjacent cities converged during a great festival in the month of Hueytozoztli, at the end of April. Here a young boy was sacrificed, while in a complementary ceremony taking place at a nearby lake a similar fate awaited a young girl, who was appropriately dressed in blue.

Many different calendrically timed rituals such as these, taking place all over the Mexica empire, generated a network of relationships in people's minds among sacred places in the landscape (particularly mountains), the activities that took place there, and the timing of those activities. Evidence suggests that those perceptions were reinforced both by the positioning of tem-

ples in the landscape and by solar alignments deliberately built into those temples. It has been proposed that the Templo Mayor was (at least approximately) aligned upon Cerro Tlaloc on the horizon to the east, that the sun would have risen more or less behind that mountain on the equinox, and that two prominent mountains on the eastern horizon from Cerro Tlaloc itself, across the next valley, aligned with sunrise on two important days when mountain ceremonies were taking place on that peak. More recent work suggests that the later phases of the temple were in fact oriented upon sunset at the feast of Tlacaxipehualiztli, which coincided with the Julian vernal equinox in 1519 and was duly recorded by the Franciscan chronicler Motolinia. Whatever the details in this case, the combination of post-Conquest accounts relating to the nature and timing of ceremonies, archaeological evidence of votive offerings at sites such as mountain shrines, and archaeoastronomical data on orientations and alignments makes a convincing case that many relationships such as these were real enough in the Mexica mind.

The Andean World in Miniature

People throughout the Andes sculpted or molded diminutive figures and artifacts small enough to be held in the hand. Many examples show an architectural layout, complete with buildings and even people, which, according to the Spanish chroniclers, was used to help people reorganize themselves spatially. Pachacuti Inca, for example, was believed to have used clay models when re-

constructing Cuzco and reorganizing its political, economic, and ritual life.

The Garden of the Sun that Pachacuti constructed in Cuzco's center reputedly contained many gold and silver figurines of animals and plants, such as maize cobs, reproduced to a high degree of accuracy. This miniature garden world was the twin of the natural world that the Incas attempted to control. This was perhaps an attempt to achieve a balance between the volatile forces of nature such as water and lightning and the more ordered forces of the cultural world. Inca stone and metal sculptures of animals and plants were also repositories of health and well-being for the herds and crops they represented. Furthermore, miniatures were thought to help with the future acquisition of the objects they represented; some even allowed the possessor to gain skills, such as weaving.

Miniatures also served as grave items and in particular accompanied sacrificial victims to their resting places on high mountain peaks. Exemplifying the duality of the Inca world, the sacrificial victims were sometimes a couple, a boy and a girl. They were accompanied by miniature household items only centimeters high, such as paired sets of serving utensils and miniature textiles carefully crafted in imitation of sumptuous full-size garments and complete with borders. The votive offerings and selection of the youths represented in miniature the world of adults. Children were believed to have special ability to communicate with the powerful Apukuna, or guardian lords, who were believed to inhabit the high mountain peaks from where they watched over the surrounding region and its people and commanded the deities of the lower hills. Communication with an Apu could be achieved through play, and miniature toys that were used by children also acquired this special power. For Inca society, human child sacrifice was considered a legitimate expression of children's special role as mediators between the physical and spiritual worlds.

THE HARVEST FESTIVAL OF HÁTUN RAIMI

Around 1550, Pedro de Cieza de León, a Spanish chronicler of Andean history and culture, described the Inca August harvest festival in which he mentioned the use of small effigies of llamas and women as religious tokens. We can only guess at their meaning.

"In the middle of the plaza they had erected . . . a great theater with tiers, covered with cloth of feathers thick with beads of gold, and great blankets of their finest wool, embroidered in gold and jewels. At the top of this throne they place the figure of their Tici-Viracocha, large and richly adorned, whom, as they held him to be the supreme god, author of all creation, they seated at the top Below this throne there was the image of the sun. . . and that of the moon, and other statues of gods carved in wood and stone. . . . Thus the Inca and the high priest and the courtiers of Cuzco and many people from the neighboring regions, after enthroning their gods, made them obeisance and laid before them many little idols of gold, and llamas of gold, and figures of women, all small, and many other jewels."

Perspectives on Petrographs, Petroglyphs, and the Historian's Craft

History is as much an art as a science. The narratives that historians craft and the interpretative insights that they offer depend as much on their ability to enter imaginatively into the past and to bring that past alive as they do on painstaking research into the evidence. Put another way, the story that a historian tells depends as much on his or her personality, life experiences, breadth of vision, and narrative powers as it does on technical expertise. It is this reality that makes history a humanistic discipline that is constantly evolving, multifaceted in ways that defy counting, and endlessly fascinating, just like the flesh-and-blood humans who research and write it.

As a small example of this all-too-often overlooked aspect of historical scholarship, we offer two entries on a common topic: rock carvings in North America. Sounds like a pretty straightforward topic, does it not? Not much room for creativity or variety of presentation there. Right? Well, let us see.

—Alfred J. Andrea

Example 1: Petrographs and Petroglyphs—The Art of Sacred Landscape in North America

Rock art was a common medium of expression for the various peoples who inhabited North America before 1500 and continued as such down into modern times. “Rock art” is a general term embracing all petroglyphs and petrographs made in or on rock surfaces. The term “petroglyph” refers to marks made by removing a portion of the rock surface by pecking, incising, or grinding. The term “petrograph” refers to marks made by adding paint or other substance to the rock surface. The term “pictograph” is also sometimes used the same way, but it more correctly refers to picture writing in any medium.

Most North American Indian rock art was made or used in a religious context. Indeed, rock art and landscape were and are inextricably linked, because rock art is believed by contemporary Native Americans to appear at places where the spirits dwell, and there is every good reason to conclude that their ancestors who dwelled in these lands before European contact believed likewise. It is never clear, however, whether the spirits inhabit a place because it has sacred markings or whether the sacred markings appear because the rock is a spirit home.

Religious Indian rock art falls into several categories: rock art created during ceremonies; rock art used in individual devotion, such as the vision quest; images of mythic beings or stories; images of ceremonies or items used in ceremonies; and depictions of religious experiences, such as visions or trances. Many Indians believe that spirits create the markings as messages to the people from the spirit world. In some cases, this may mean that the rock art is very old and thus associated with the time before people. It may also have reference to people creating rock art while impersonating a spirit being. Shamans and other spiritual leaders as well as ordinary people might take on the role of a spirit being to validate or publicize their visions. In that role they might make rock art on behalf of the spirit being. A widespread belief is that rock art will reveal a message about the future to holy men or women who have fasted and prayed nearby.

At other times the rock art will convey a sacred message to an ordinary person, but he or she may need the help of a religious specialist to understand it. These beliefs assume that the rock art mysteriously changes to convey the correct message or, from another perspective, that the spirits change how the viewer sees the image.

Some rock art conveyed simple messages, such as a group's whereabouts, and some recorded warriors' exploits or a group's visit to a particular place. However, because all activities, including warfare and travel, traditionally included elements of ritual and prayer, one cannot draw a strict line between secular and religious rock art.

Some rock art in the Americas is thousands of years old and is thus difficult to interpret. The further back one goes in time, the less likely it is that historically recorded information will pertain to the rock art. Nevertheless, some ancient rock art can still be recognized as religious because it shows ceremonial activities or religious symbols that persisted into historical times, such as the thunderbird. Rock art comprising the abstract designs and colorful images typical of trance states is often assumed to have a religious origin. An example is the painted rock art of southern California. Religious art often is highly symbolic or metaphorical, making its interpretation especially difficult. In some cases, tribal historians have retained detailed knowledge of old symbols and are experts on their meaning.

Much Indian rock art depicts myths or mythical beings. Caves in Missouri and Wisconsin depict a culture hero called Red Horn. Petroglyphs in the Cave Hills of South Dakota illustrate myths connected to eagle trapping, and others in western Wyoming show mythical beings such as Water Ghost Woman. Images of kachinas (spirit beings that control rain, fertility, and well-being) appear in southwestern rock art.

Researchers have yet to develop reliable methods for determining the age of rock art. Most promising so far is accelerator mass spectrometry-aided radiocarbon dating. Tiny amounts of pigment can be collected and dated through the radiocarbon method but only if the pigment contains residues of organic material such as charcoal, albumin, or blood. It may eventually be possible to measure the rate of

chemical change to the rock surface initiated when the surface was broken in creating a petroglyph. Dating methods in use now include measuring the age of buried archaeological material that covers rock art panels or contains bits of fallen rock art; measuring the age of materials covering rock art, such as wasp nests or cliff swallow nests; and correlating the stranding of rock art panels with episodes of erosion. These methods yield only minimum ages rather than absolute ages.

Other clues to the age of a petroglyph or petrograph come from the items depicted. If an extinct animal is pictured, the rock art presumably was made before the species died out. If European trade goods or horses are shown, then the image must have been made after those items arrived in the Americas. Sometimes an unusual motif found in rock art is also found in portable objects from the same area that can be more readily dated.

—*Linea Sundstrom*

Example 2: Petroglyphs and Petrographs in North America

Petroglyphs and petrographs are rock-cut designs or images made by pecking, incising, abrading, scratching, or otherwise engraving a figure or image on a rock or cliff face and are found throughout North America, although the majority are found in California, the Western Plateau, the Great Basin, the Plains, and the Southwest regions. They apparently date from approximately 2000 BCE (or slightly earlier) to the beginning of the twentieth century. Because petroglyphs and petrographs are engraved in rock, it is exceedingly difficult to accurately date individual designs or images, and some examples may date to an earlier time.

Petroglyphs or petrographs were cut through rock surfaces darkened by either "desert varnish" or patina, which is a thin accretion of manganese, iron oxides, clay minerals, and other elements, so that the resulting imagery contrasted with the surrounding rock surface. Over time a new layer of the patina formed on the engraved imagery, resulting in contrasting shades of varnish. In other areas the images were incised or carved into soft rock surfaces, such as

the sandstone petroglyphs and petrographs of the Plains region and Southwest desert.

Based on archaeological and oral tradition evidence, petroglyphs and petrographs were made for a variety of reasons, including economic, social, and religious. Sites that contain petroglyphs and petrographs, for example, may designate sacred sites where communication with the supernatural was possible or otherwise important localities in the landscape, such as sites associated with important mythical events. Likewise, these images have been made in the context of vision quests and puberty, curing, and hunting ceremonies; to mark social boundaries and land-use rights; to document important events; and to represent status objects.

A large group of petroglyphs, all versions of a single “horseshoe” symbol carved in high relief, have been found on an isolated volcanic peak in California. The more realistic ones appear to represent female genitalia, whereas the rest seem to be more abstract versions of the same motif. Archaeological evidence indicates that similar motifs are located in other parts of southern California, and ethnological evidence indicates that the same “horseshoe” symbol survived until recently as a magical element in the Diegueno Native American girls’ initiation ceremony.

Along the Salmon River basin in the Western Plateau region, petroglyphs and petrographs commonly portray human and animal stick figures as well as dots and dashes. Common animals depicted include elk, deer, mountain sheep, and dogs. On the other hand, in the Sweetgrass Hills, Little Rock, and Little Belt Mountains of the Plains region, the imagery often consists of highly abstracted symbols that appear to represent masks, mazes, and geometric shapes. Some date to the Late Archaic, such as the example found in the Bighorn Basin of Wyoming at a large site known as Legend Rock.

In the Southwest region, petroglyphs and petrographs are not as abstract, and in fact many are highly specific in their imagery. For example, there are several depictions of Puebloan kachinas, including the Hunchback deity, sun shields with macaw feathers, and heart lines in animal figures, as well as stylistic resemblances to known prehistoric kiva murals. Other Puebloan traits found in petrographs and petroglyphs include cane arrow shafts, macaw images, sandals, close-coiled basketry, tubular pipes, tablitas, masks, gourd dippers and canteens, woven cloth, and tools for spinning and weaving.

Society and Culture—The *Longue Durée* and Innovation

The terms “society” and “culture” are as vague and all-encompassing as any two allied words can be, but regardless of their ambiguity and plasticity, or perhaps because of these qualities, they lie at the heart of historical research and writing. Viewers of the History Channel might be led to think that the study of history consists mainly of tracing the movements of armies, plotting the rise and fall of polities, and analyzing the actions of so-called great men and women. While such phenomena and people are historically important, it has been, is, and always will be the underlying cultural attitudes and values as well as modes of social behavior and organization that provide the fabric of history. If we fail to understand a society’s culture, we fail as historians.

During the period from 1000 to 1500 CE, the vast majority of humanity lived in what we might correctly term traditional societies. That is, such societies functioned according to norms and in ways that had been established centuries and even millennia earlier, and those living within these societies were not aware of there being any opportunity for meaningful change in the ways of life. To be sure, natural disasters occurred; invading armies came and went, often destroying much in their wake; and states experienced every sort of fortune and fate. Regardless of such external stimuli, however, modes of expression and behavior tended to remain constant for most humans in most societies across the globe. As with just about everything else, the French have a term for this phenomenon: *longue durée*, roughly translated as “long-lasting reality.”

One of those realities was that states, with the possible exception of small mercantile city-states, such as Venice, and the early Mongol empire, had economies based on agriculture. No matter how large and productive a state’s industrial and commercial enterprises might be and no matter how populous and vast its cities, its basis for wealth was land and products produced from that land. Consequently,

whether recognized as such or not, the peasant was the backbone of society, and agrarian villages were its vital organs. This anatomical metaphor might be strained, but it describes a reality that is often overlooked if we concentrate solely on the great events of this 500-year era that dominate the pages of textbooks. Without farmers’ paying rents

No matter how large and productive a state’s industrial and commercial enterprises might be and no matter how populous and vast its cities, its basis for wealth was land and products produced from that land.

and taxes, states would cease to function; without farmers' feeding the ever-hungry markets of Tenochtitlan, Hangzhou, Baghdad, Timbuktu, and numerous other great centers of commerce and industry, cities would wither away. As we might expect, despite this age's unquestioned innovations, some of which had long-term revolutionary impact, the values espoused by most in these agrarian-based polities were conservative. Steady and traditional are the hallmarks of most successful farmers and the societies they support.

Such conservatism was evident throughout settled societies around the world. As had already been the case for millennia, empires and smaller states, almost without exception, were ruled by monarchs who claimed some sort of heavenly or divine mandate. Social classes tended to be ordered according to strict hierarchical standards, even in religious cultures such as Judaism, Christianity, and Islam that taught the equality before God of all believers. It is equally true, however, that the rising number of large and economically complex cities allowed some social fluidity, but urban dwellers were a small minority in the aggregate. Likewise, gender relations and the relative power of men and women, in most but not all settled societies, also tended to be weighted in favor of men. Indeed, there is reason to conclude that upper- and middle-class women in China tended to lose autonomy during this half millennium. On the other hand, West African women, both Muslims and those practicing the ancient religions, seem to have much more freedom than most of their sisters living in settled communities throughout the rest of Afro-Eurasia.

As already suggested, of course, the period 1000–1500 was not static, and cultures and societies experienced changes in response to both external and internal stimuli. In sub-Saharan West Africa, for example, Islam was making major inroads in the various commercial states, such as Mali, and with this new religion came new cultural norms. But old ways died hard, and more often than not the values and practices of Islam in sub-Saharan Africa, as elsewhere, were married to traditional ways of life.

To this point we have discussed settled, or so-called centered, societies that were based on agriculture and produced states. Nomadism as practiced by pastoralists, however, was also a way of life for a significant number of people, especially on the great Eurasian steppe that stretches from Manchuria and Siberia to eastern Europe. Although their numbers were small relative to their settled neighbors, these peoples on the periphery of Eurasia's great states proved to be important driving forces in the history of this great landmass during these five centuries, and some of them even became great state builders once they settled down (as entries grouped under the themes of "Politics and Statecraft" and of "War and Diplomacy" demonstrate). Regardless, their nomadic cultures and societies were conservative, even though many of their values and ways of life differed substantially from those of settled agriculturalists. For example, gender and social relationships tended to be much more egalitarian. Just as significant, when, as happened on a fairly regular basis, a confederation of nomadic pastoralists would conquer or settle in part or all of a neighboring state, such as the various Turkic

peoples who settled in western Eurasia or the Jurchen (Ruzhen) in northern China, they invariably underwent a process of acculturation in which they adopted and adapted to their ways of life the cultures of the peoples into whose lands they had moved.

All people, whether nomads, village-dwelling farmers, or urban dwellers, have richly variegated cultures that allow them to make the world a comfortable, understandable, and enriching place in which to live. This was true for tens of thousands of years before 1000 CE, just as it is equally true today. A fair number of the entries in this section will demonstrate some of the many different ways in which people around the globe gave expression to their artistic sensibilities and their need to shape the world about them.

One aspect of human culture that is of prime interest to the historian is the manner in which it is transmitted from one generation or group to another. The half millennium under discussion here was noted for its proliferation of schools of every sort around the globe. By their very nature, most schools before the modern era (and maybe even so today) were fairly conservative insofar as they existed primarily to transmit values and received wisdom and knowledge. Yet some of these centers of learning, such as the great madrasas within the Islamic metropolises and capital cities, Neo-Confucian academies in China and Korea, and the new universities of Latin Christian Europe, could be and were mediums for both the transmission of new ideas from outside and the generation of innovative ideas from within. Schools, especially those centered in large cities, at times functioned as vehicles for social and cultural change. In this section we shall see some of those centers for religious and secular learning, while other entries, grouped under the themes “Thought and Religion” and “Science and Technology,” will indicate the innovations they helped generate and disseminate.

In conclusion, although most people who lived during the period from 1000 to 1500 inhabited miniworlds and societies that were conservative in their ways, cultural change did happen, and much of it was of historical significance.

—Alfred J. Andrea

■ Introduction: Families, Hierarchies, and Class Relationships—Cultures of Lordship

Sima Guang (1019–1086) wrote in his sweeping history of China known as *The Comprehensive Mirror to Aid in Governance* (*Zizhi tongjian*) that because humans cannot govern themselves, they necessarily need a ruler who is able to prevent violence, protect the lives of people by removing all harmful matters, and prevent disaster by rewarding good and punishing evil. Such a

notion was almost universal throughout the world in the period 1000–1500, whether that ruler, or lord, was an emperor, a king, a feudal prince, a tribal chief, a manorial lord, a slave master, or a clan elder. Lordship, in which the many were governed (and presumably protected) by the few and those who served these lords (and, in rare exceptions, female leaders), was

the norm. As Sima Guang correctly noted, conditions were such that this type of rule was perceived as necessary, and it probably was necessary.

More than that, lordship was underpinned by ideology. Whether the ruler was the Son of Heaven as in China, the direct descendant of the Sun Goddess as in Japan, the Shadow of God on Earth as was the claim of the Abbasid caliphs, or a living god as was claimed by the Incas, emperors and kings, as well as governing empresses and queens, had an authority that was based on cosmological principles and supported by religious ritual. As a Norman polemicist known variously as the Norman Anonymous and the Anonymous of York (see “The Christian God-Anointed Monarch”) wrote around 1100 in support of the unfettered powers of kings, “The king is consecrated and made like unto God.”

In like fashion, lords and ladies, chiefs and elders, masters and mistresses of lower rank who also wielded power of any sort over others, and in many cases a power free of any controlling authority from above, quite often enjoyed the comfort of believing that their power was likewise part of the natural order and, more often than not, divinely instituted or blessed.

—*Alfred J. Andrea*

Varieties of Hierarchies and Class in Sub-Saharan Africa

By 1000 the Bantu-speaking peoples, the most influential sub-Saharan African language group and ethnic community, occupied most of Africa south of the equator. As a result of centuries of outward migration in search of fertile lands to cultivate, the Bantu formed new settlements and gradually organized their societies. With the development of increasingly complex societies, powerful states emerged in sub-Saharan Africa around 1000 CE that featured elaborate hierarchies and clearly defined varieties of classes: ruling elites, administrative officials, priests, merchants, artisans, peasants, and slaves.

Prior to 1000, most sub-Saharan African peoples settled in communities with populations averaging about 100 people. Early Bantu societies governed themselves not through an elaborate hierarchy of ruling elites and officials but rather through self-sufficient kin-based societies. Therefore, the primary unit of social organization in these small autonomous communities was the extended family. The male heads of families constituted the community’s council that managed the group’s affairs. A chief was chosen from among the most prominent family heads, and it was he who represented the community in interactions with neighboring settlements. Some kin-based community populations expanded to include thousands and hundreds of thousands, but with growth came challenges.

Growing populations strained resources available to the community such as fertile land and wild animals. Also, conflicts among neighboring settlements became more frequent as societies expanded and interacted with one another. Some societies became powerful kingdoms by conquering and consolidating smaller communities. Threatened by these stronger kingdoms, various small communities marshaled their military forces together and selected a powerful chief to lead them. Although family-governed communities did not completely disappear with the rise of powerful sub-Saharan chiefdoms and kingdoms—some persisted well into the nineteenth century—kin-based societies were gradually replaced by chiefdoms, large kingdoms, and

Mapungubwe, situated south of the Limpopo River in South Africa. (Sara Atkins)

powerful states in the centuries after 1000 as Bantu peoples developed more formal structures of government not yet seen in sub-Saharan Africa.

A common feature of these powerful sub-Saharan African states was a ruling class of elites. The acquisition of wealth brought about the development of a hierarchy of elites that resulted in significant visual changes within the state's social and physical structures. Political elites based their power on a combination of mixed farming and cattle herding and long-distance trade in metals such as gold, copper, iron, and tin. At Mapungubwe, situated south of the Limpopo River, hierarchy became visually expressed for the first time as the ruling elite clearly distinguished itself from various other classes. Mapungubwe's rulers built huge walls constructed of stone around their residences, which were located on a hilltop that overlooked the surrounding valley. It was in the valley, with a clear vantage point of the ruling elite's palaces perched on the hilltop, that the commoners resided in their traditional homes. At Great Zimbabwe, Mapungubwe's successor, the ruling class erected two impressive stone structures that housed the powerful state's elite. These structures are indicative of an increasingly complex society deep in the interior of sub-Saharan Africa that possessed the resources to invest in such elaborate and expensive construction projects.

Scholars estimate that some of these powerful sub-Saharan African civilizations supported tens of thousands of people. These states generated not only a ruling elite but also various other social classes. Administrative officials and priests served to reinforce the political and sacred power of the ruling class. Merchants and artisans provided the exotic goods and symbols of high culture that legitimated the ruler's position in society. Peasants and slaves offered tribute and increased agricultural production, which enhanced the elite's wealth. Each of the various classes of powerful sub-Saharan African states provided the symbolism and accumulated the wealth that enabled the ruling class to project order and legitimacy, which therefore solidified its role as the carrier of civilization.

—William Hardy

➤ IBN BATTUTA DESCRIBES COURT PROTOCOL IN MALI

During 1352–1354, Abu Abdallah ibn Battuta (1304–1368/1369) traveled from Morocco to sub-Saharan West Africa. There he visited Mali, a trade empire where Islam had taken root among its elites. In his *rihla*, or book of travels, he describes the protocol surrounding Mansa (King or Sultan) Sulaiman (d. 1360).

“The blacks are the most humble of men before their king and the most extreme in their self-abasement before him. They swear by his name, saying, ‘Mansa Sulaimanki’ (the law of Mansa Sulaiman). When he calls one of them . . . the man invited takes off his clothes and wears patched clothes, takes off his turban, puts on a dirty cap, and goes in raising his clothes and trousers up his legs half-way to his knees. He advances with humility looking like a beggar. He hits the ground with his elbows, he hits it hard. . . . When one of them speaks to the sultan and he (Mansa Sulaiman) gives him an answer, he removes his clothes from his back and throws dust on his head and back.”

Hierarchy and Class in the Islamic World

Umma, the Arabic word for “community,” makes no distinction between the citizens of individual cities or rural districts and the worldwide Islamic community. During the Umayyad (661–750) and

» SULTANS AND SUBJECTS

“Sultan” (one who has authority) was the preferred title of many Arab and Turkic Islamic rulers. It generally signified the rank of a Muslim ruler who claimed full sovereignty over a large region but was subservient to the caliph. One exception was the Ottoman sultans who actually claimed the caliphate in the period 1517–1875. The title of sultan referred not only to the actual ruler and head of the dynasty but also to the larger extended ruling family. Essentially, sovereignty belonged to the dynasty as a whole, and any prince or other powerful member could claim the title and be seen as an independent ruler who merely owed formal allegiance to the head of the family. While the overwhelming majority of sultans were male, several female sultanas such as Shajar al-Durr (r. 1250–1257) in Egypt and Radiyya Sultan (r. 1236–1240) in Delhi, India, proved that the most important aspects of a ruler were that they maintained security, upheld Islam, provided charity, and acted as philanthropists.

The sultan demanded absolute power as the secular leader of a region, and subjects were expected to follow his or her commands unquestioningly. Nevertheless, the sultans’ power rested on the ability to rule strongly and justly. A sultan who failed to uphold justice or defend her or his territory or did not perform charitable works for her or his subjects would lose considerable prestige and might then be disobeyed in favor of a strong rival leader.

—Julie T. Abouzelof

Abbasid caliphates (750–1258) there existed such uniformity in the laws and institutions that bound Muslims to the larger umma that one can speak of a virtually universal society stretching from the Atlantic to China. Class and hierarchy structures in the Middle East and North Africa contained many of the characteristics of the Islamic umma dating as far back as the seventh- and eighth-century Islamic conquests. Moreover, this social structure remained fairly unified long after many other regions were incorporated into different political, religious, or social systems.

The highest class of the social hierarchy consisted of the caliphate, ruling families, their retainers, and scholars and jurists, both religious

and secular. The middle class was largely urban and consisted of merchants, craftsmen, and other skilled and/or educated professionals, with specific rank being determined largely by the economic status or social respect accorded to the individual or profession. Since both the Middle East and North Africa were strictly patriarchal, adult males enjoyed significantly higher social status than adult women or children of either sex.

The lower classes were the urban poor and rural peasants. While servants held a low status, the class position of slaves was dependent on the status of the family by whom they were owned. Thus, the slave of a rich family could have a higher status than a poor freeman. Soldiers had a similarly ambiguous social status, which depended on whether they were free or slave soldiers and also depended on the specific military climate of the region and period. At the bottom of the social hierarchy were nomads and semi-nomads, despite Islamic roots in Bedouin (desert dwellers) tribal society. During the Umayyad and Abbasid periods the vast majority of people in the Middle East and North Africa lived in rural areas in villages tied to agricultural production. Villages were traditionally autonomous in the sense that they were largely self-governing. As such, Christian and Jewish villages were allowed to practice their own systems of law. Most of the time, peasants and nomads appear to have lived in a symbiotic relationship with each other. Nomads depended on the grains and fruit that the peasants provided, while the peasants bought the animals, wool, and other animal products produced by the nomads.

The Ayyubids (1171–1250) were responsible for a major rise in the status of Egypt in the Sunni world. Under their rule, Cairo became one of the major centers of Sunni learning, actively recruiting scholars from Syria, Iran, and Iraq, especially in the wake of early-thirteenth-century Mongol invasions of these areas. By the mid-thirteenth century, Cairo had become the cultural capital of the Muslim world, a status that was sealed in 1258 when the Mongols destroyed what was left of Baghdad. For almost three centuries, Cairo would remain the center of Islamic scholarship.

Muslims had a higher social status (if not necessarily economic status) than other religious

groups in the Middle East and North Africa. The status of Sunni, Shia, and other Islamic groups depended on which group was the majority in a specific region. In North Africa and much of the Middle East the religious majority has traditionally been Sunni. Exceptions to this include regions such as the Iranian Plateau and dynasties like the Fatimids in Tunisia (909–973) and Egypt (969–1171), both of which were Shia. The status of Jews and Christians was that of “People of the Book,” meaning people who believed in the God of Abraham and therefore shared a common religious background with Muslims. As such, they enjoyed *dhimmi* status, having at least implicitly entered into a contract of toleration (*dhimma*) with Islam whereby they could practice their faith and pursue their traditional professions and crafts but with some restrictions on their public behavior. Some Jews and Christians did rise to important posts in several Islamic courts. Adherents of all other religions were officially classified as polytheistic unbelievers and had virtually no rank in the social hierarchy except as slaves, but in fact Zoroastrians and other so-called polytheists were often tolerated.

Death and Burial in the Latin East—Evidence of Cross-Cultural Interchange?

Death and burial in the Latin, or Frankish, East is a subject that has not been studied in great

One of the slab tombs found in the crusader cemetery at Atlit, its incised decoration depicts a Latin cross and the tools of a stonemason, namely the hammer (left) and set square (right). The hammer appears to be a type used in crusader architecture in Europe, Anatolia, Armenia, and Mesopotamia. This likely means that the stonemason who constructed this tomb used the hammer as both tool and model. It appears that one stonemason was honoring another in death. (Jennifer A. Thompson)

detail up to now. In general, studies of cemeteries and of burials have been limited to studies of skeletal remains, ceramics and artifacts found in burials, and the type of grave in which the remains were found. These three areas have been considered separately but have never been combined to form a cohesive picture of the burial customs of the peoples of the Latin East.

There are several different types of burial found in the Latin East. It is also important to distinguish between grave types and tomb types. Graves are the part of the burial located below ground, whereas the tomb is the burial superstructure. Most of the burial sites in the Latin East lack tombs, although there are a number of well-preserved tombs to be found throughout the Latin East.

The site with the largest number of well-preserved tombs is the crusader cemetery at Atlit just south of Acre (Akko) in Israel. Here, there are several hundred tombs located in a walled cemetery located outside the fortified walls of Pilgrims' Castle, one of the most important castles belonging to the Knights Templar. Within the cemetery, there are five types of tombs and one type of grave. None of the burial sites has yet been excavated, so it is not known what type of grave was used in those burials.

Similar tomb types are generally grouped together in separate areas of the cemetery, and the largest and most elaborate tombs have been found in the portion of the cemetery closest to the road leading to the gates of Pilgrims' Castle. It is likely that these belonged to the higher classes of society, whereas the least elaborate belonged to the Knights Templar, each of whom had sworn a vow of poverty regardless of the class from which he came, and to the poorer sections of society.

Do these and other burial sites in the Latin East present any evidence of cross-cultural fertilization? It appears from the evidence that most of the burial customs and grave and tomb types of Frankish colonists had a European influence. For example, pottery in these burial sites can be traced back to the medieval French practice of depositing pottery with the deceased. Nevertheless, there is some evidence of cross-cultural influence.

Frankish Cyprus and Latin settlements near Constantinople and on mainland Greece present some evidence of cultural interchange. At Corinth, in the former principality of Achaea, there is evidence that the Greek Christian population adopted some Frankish burials rites, such as inclusion of pottery with burials. Conversely, at Galata, a Genoese colony at Constantinople, some of the tombs at the monastery of Saints Paul and Domenico show Byzantine influences, such as Byzantine crosses.

There is even some indication that Islamic influences crept into the burial rites of the Frankish population of the Latin East. At the crusader cemetery at Atlit, one type of tomb had a border of rough stones with an upstanding stone at either the head or the foot of the grave and possibly at both ends. The tomb was then likely plastered over. This manner of tomb construction is similar to the Muslim graves that are described from ethnographic studies of Muslim villages in Palestine in the early to mid-twentieth century.

The excavation of burials has become a delicate subject in much of the world over the last few decades. It is no different in the area of the Latin East, especially in the state of Israel. With restrictions in place that curtail the excavation of burials, it is unlikely that new information on death and burial in the Latin East will come from the crusader sites in Israel. Therefore, precise information regarding the status of people buried under the tombs at Atlit is not available because the tombs have never been excavated, nor are they likely to be in the near future.

Foot Binding of Chinese Women

The Chinese custom of foot binding became widespread between 1000 and 1500 CE. Apparently the practice began in court circles, but by

the Ming dynasty it was common among all classes. The procedure was excruciatingly painful. Although the age of the girls varied, at some point between their fourth and eighth year the grandmothers and mothers of the household would begin applying tight bandages of silk or cotton to the girls' feet. The purpose was not only to stop growth but to reshape the little feet as well. As the binding was tightened, the four small toes were folded under the foot and the arch pulled inward until the ball of the foot touched the heel. Walking was always difficult for women who had undergone the procedure, and the discomfort confined many to their homes. The crippling effect was not limited to feet. Modern scientists have noted that a disproportionate number of women with bound feet suffered from crippling osteoporosis.

The origin of foot binding is a mystery. During the Tang (618–907) and Song (960–1279) periods, some sources linked foot binding to an ancient folk tale that described Daji, a female wizard with the body of a fox, who used her tiny paws to seduce King Zhou (d. 1027 BCE), a tyrant of the Yin (late Shang) dynasty. His resultant sexual obsession led to the ruin of his kingdom. Other sources repeated the story of the heroine Wu Yueniang, a southern Chinese girl, who attempted to assassinate the exceptionally brutal ruler of the Sui dynasty, Emperor Yang Guang (r. 605–617), who selected young girls with small feet from the south to serve him. Yueniang broke her insteps and hid a knife under one of her bound feet. Her attempt failed, and the enraged emperor thereafter forbade women with bound feet to be in his company. But her hometown women, in honoring Yueniang and demonstrating their defiance to the tyrant, volunteered to get their own feet bound. Other tales suggest that foot binding in China was inspired by Buddhist art, which often depicted barefooted females dancing on lotus petals. Another story, that of Yaoniang whose name means “lady with high eyebrows,” thereby implying her non-Chinese ethnic identity, told of how Emperor Li Yu (r. 961–75), the last ruler of the Southern Tang dynasty, enjoyed having Yaoniang wear lotus-shaped golden shoes and performing her toe dance on a golden lotus stage.

These latter sources thus offered an explanation of why a bound foot, which ideally was less than three inches (7.5 centimeters) long, was called a golden lotus.

Despite these folktales, concrete and convincing evidence of foot binding as a popular practice in China before 1000 CE remains problematical at best. All solid evidence indicates that foot binding was largely a literary or artistic motif before the turn of the millennium and not a widespread reality, since neither Buddhist women of non-Chinese origin nor southern Chinese women had their feet bound. The fact that foot binding became a pervasive social practice in the era of the Northern Song dynasty (960–1126) suggests that the court ladies of Northern Song were not as free or as athletic as their polo-playing counterparts in the Tang court. It also points to the increasing prosperity of China's growing merchant and artisan classes, whose women were having their feet bound in increasing numbers as their labor became less valued or necessary.

Even though erotic associations remained strong, foot binding also became associated with Chinese aspirations for just government following the collapse of the Northern Song dynasty in 1126, when Jurchen (Ruzhen) invaders established their dominance over northern China. Many Chinese, including imperial bureaucrats and intellectuals, followed the Song court to southern China. While migrating southward, some intellectuals recorded their cultural shock caused by the big feet of the southern Chinese and ethnic minority women they encountered. Moreover, their writings revealed a contemptuous attitude toward both the foreigners who had defeated them and the people of the South, among whom they were now living, that they expressed by ridiculing the natural feet of their women. This indicates that foot binding had become socially practiced at least among elite ladies in northern China during the Northern Song period and began to spread among the southern Chinese in the Southern Song era (1127–1279).

China's Mongol rulers of the Yuan dynasty (1279–1368) discouraged Mongol women from binding their feet but were tolerant of the practice by the ethnic Chinese. The Mongols implemented a militaristic government to replace the

► PU SA MAN (A POEM OF LOTUS FEET)

Su Shi (1037–1101), better known by his alias Su Dongpo, a poet of the Northern Song dynasty, recorded his enjoyment of a courtly dance in this lyric poem, which was set to music.

Step by step, her lotus feet spread fragrance,
Blowing and fading;
Wrinkle after wrinkle, her skirt flies,
Approaching and disappearing.
I can still sense the wind,
Twisting and turning;
Where she is hiding now,
I cannot see.
Standing on one toe,
She is as solid as a palace building,
Pairing them together,
She trembles as if she is sleepy;
I cannot find words to describe
Their beauty and delicacy;
They can only be appreciated,
Only when I hold them in my palm.

well-established Chinese civilian bureaucracy and degraded Confucian scholars to the ninth rank in a social hierarchy that had a scale of 1 to 10: below prostitutes and above only vagabonds. Chinese intellectuals were so reduced in status that women’s bound feet became the only ego-boosting treasure left to them as they suffered under the repression of the uncivilized others.

Foot binding became widespread during the Ming era (1368–1644). The first Ming emperor, Zhu Yuanzhang, also known as the Hongwu Emperor (r. 1368–1398), was born a peasant. His wife Empress Ma, who was loved by many Chinese commoners, had big feet, but few (if any) women emulated her. Foot binding had become a rite of passage, an expression of female commitment to virtue that became more widespread under Zhu, one of the most proactive Chinese rulers when it came to regulating the morality

of his subjects. Women became restricted in an ever-shrinking space in the inner circles of the family.

Meanwhile, the growth of urban and commercial culture accelerated the trend of degrading women as commercial objects. The circulation of erotic literature, such as *Jin-Ping-Mei* (the title of which incorporated the names of the male character’s three concubines Golden Lotus, Vased Flower, and Plum Blossom), glorified to some extent the polygamy of the neo-Confucian scholar-officials and the urban rich in which a husband could be sexually obsessed with the golden lotuses of his numerous concubines. Bound feet became a norm for judging a woman’s social status and her virtue. Normal feet revealed a woman’s low status as a domestic servant, a poor peasant, or a non-Chinese barbarian. Bound feet also became a prerequisite for a girl to marry a suitable husband. The statement “you would never find a husband with your unbound feet” was the most coercive persuasion that a mother could use to force her very young daughter to go through the painful process of foot binding. At the same time, the most highly valued feet became increasingly smaller and more radically curved, and lotus shoes became ever more delicate and decorated. The trend continued into and throughout the Qing period (1644–1911), and was finally abolished by the government of the newly established Republic of China in 1912.

With the triumph of another barbarian people from the north in 1644, history repeated itself but with a twist after the Manchu (Qing) empire was established in China. From the very beginning, the imperial authority ordered Chinese men, under the threat of death, to shave their hair in front and wear a Manchu braid (queue) and forbade Chinese women to bind their feet. Chinese men, under pressure, shaved their heads and wore the hated plait, but Chinese women persisted in binding their feet. Emperor Kangxi (r. 1661–1722) ceased enforcement of the order, although foot binding remained prohibited for Manchu women. In time, however, some Manchurian women accepted foot binding as their dynasty became sinified. In response to this phenomenon, Confucian scholars coined the

phrase “men-surrendered-and-women-resisted” to signify their delight in the partial victory of Chinese civility over alien barbarianism.

Few Confucian scholars questioned the moral implications of foot binding. Indeed, many defended the practice as a cultural treasure. Nonetheless, it is inaccurate to think of the practice as something forced upon women by males. Modern scholars point to records that reveal that many Chinese women were staunch supporters of foot binding and full participants in the creation and maintenance of the cultural gender roles. Foot binding was a measure of a woman's status, virtue, beauty, security, and sexuality. For many, it was a source of self-esteem. It was only the reluctant interactions of the Chinese elite with Western culture in the late nineteenth century that produced indigenous criticism of this tradition.

The Christian God-Anointed Monarch—Byzantium, Ethiopia, Serbia, Bulgaria, Russia, Armenia, Georgia, and the Latin West

Christianity defined not just the religious identities but also the governing ideologies of many medieval cultures. The concept of a God-anointed sovereign, with secular and sacred powers, was integral to Byzantium and appeared to varying degrees in Western Europe, the Eastern Christian kingdoms, and Ethiopia.

In the Byzantine empire, the emperor and the Church were closely united. The proximity of the imperial palace, the Bukoleon, and the adjacent patriarch's seat, the Church of Hagia Sophia, was echoed in the sacrosanct nature of the imperial office.

In 629, Emperor Heraclius (r. 610–641) changed his title from Emperor Caesar Augustus, which had underscored continuity with imperial Rome, to *Basileus*. In ancient Athens this title was borne by the official in charge of public worship and criminal proceedings. Thus, he now stressed the divine grace that enabled his rule. In the ninth century, Basil I (r. 867–886) emphasized that the sovereign should embody an image of God for his subjects to imitate. Among the emperor's adulations were *Christos Kyriou* (anointed of the Lord) and *Zosa Eikon Christou* (living icon of Christ).

The latter expression is particularly telling. Icons are images that through their likeness allow what they represent to become present on earth. Just as a painted icon of Christ by the altar made Christ present during Communion, the emperor, as a living icon of Christ, sat on the throne, ruling in Christ's place. Like his holy prototype, the emperor mediated between the divine and the human and personified the moral, judicial, and political voice of God on earth.

Elaborate coronation rites celebrated the ascendancy of the emperor to this role. The *Book of Ceremonies*, written by Emperor Constantine VII Porphyrogenitus (r. 913–959), describes the coronation ritual of the tenth through twelfth centuries and emphasizes the emperor's sacerdotal powers, permitted to no other layman. The emperor-elect, clothed in special vestments, entered the imperial door of the Hagia Sophia, prayed before the *chancel* (the enclosed space around the altar), lit candles, and ascended to the *ambo* (the ecclesiastical pulpit) with the patriarch. Here, he attained the imperial insignia, was crowned, and addressed the people. He then went to his throne within the church, where dignitaries filed past, prostrating themselves and kissing his knees. An interesting footnote to this ritual is the *akakia*, a pouch filled with earth that the emperor held in his hand. It reminded the monarch that while the office

elevated him to a divine icon, his body remained human.

In the twelfth century, imperial unction became part of the coronation. Echoing the anointing of King Solomon, it served to align the emperor with the Davidic kings of the Bible. A fourteenth-century treatise transcribes the prayer of the patriarch when he marks the cross: “deign to anoint with the oil of gladness your faithful servant. . . . Endow him with power from on high . . . bless him . . . [to] whom you have entrusted the earthly kingdom.” This unction gave the emperor the unique status of *epistemonarches* (supreme regulator of ecclesiastical discipline), as the twelfth-century canon lawyer Theodore Balsamon wrote: the emperor was allowed within the holy sanctuary, he could judge the patriarch, and he was the living law, with power over his subject’s souls as well as their bodies. Near the end of the Byzantine empire, however, unction became increasingly controlled by the Church. The direct union between the ruler and God became diluted, transforming the iconic relationship into a vague symbolism, more like what predominated in the West.

In Western Europe there was no universal acceptance of divine kingship as in Byzantium, although many concepts, such as God-granted monarctic power, were similar. The West lacked the Byzantine intimacy between the Crown and the Church, with the Alps physically dividing most of Europe from the Roman papacy. This disjuncture between the *sacerdotium* (priesthood) and the *regnum* (royal power) was a source of ceaseless debate in the medieval centuries.

The tenth-century Ottonian era, however, started Europe off on a strong note of sacral kingship. The Synod of Hohenaltheim in 916 dubbed the king *Christus domini* (anointed of the Lord). Ottonian emperors styled themselves as theocrats, even copying Byzantine attributes and intermarrying with Byzantine nobility. Ecclesiastical royal anointing, which included investment with the secular implements of crown, sword, and scepter, rendered the king semiholy: to oppose him would be sacrilege. The Ottonian rulers appointed politically powerful bishops, whose loyalty stabilized the empire, and after Otto I (r. 936–973) deposed Pope John XII (r. 955–964), they assumed the right to choose popes as well.

By the middle of the eleventh century, this custom of the royal investiture of bishops began to cause problems, since laymen, rather than the Church, were authorizing ecclesiastical power. Tensions increased when King Henry IV (r. 1056–1106) and Pope Gregory VII (r. 1073–1085) chose rival candidates for the bishopric of Milan. Gregory considered kings mere policemen and outlawed the practice of laymen—even royal ones—investing churchmen with their holy office. In 1075 he released the *Dictatus Pape* (*Proclamation of the Pope*), which placed popes above human judgment and gave them the right to depose emperors. To underscore this, Gregory excommunicated Henry. These so-called Gregorian Reforms were contested by a theological tract of circa 1100 written by an anonymous Norman cleric. He claimed that the king was superior to a priest as a representative of Christ since he echoed Christ’s divine nature, whereas the priest echoed Christ’s human nature. Thus, the king was essentially elevated to heaven, since all earthly power was inferior to his.

Many polemical texts on both sides of the issue were written over the next several centuries as the empire and papacy fought for theoretical supremacy, but in essence the Gregorian Revolution had dealt a mortal blow to Western imperial theocracy. At the same time, however, popes never gained in reality the full theoretical powers that Gregory VII and his successors claimed over secular rulers. Moreover, by the late thirteenth century a number of kings were able to gain wide-sweeping control over their national churches and even to claim successfully that they ruled by God’s grace, although their claims and powers never rivaled those of the earlier Ottonians.

The smaller Christian states in the East were both aided and harassed by the Byzantine and Western superpowers as they struggled for independence and fought against Islamic or Mongol invasions. The short-lived kingdoms and empires that emerged generally followed the prototypes of either the iconic rulers of Byzantium or the anointed kings of the West.

The Serbian empire (1346–1389) under Stephen IV Dushan (r. 1331–1355), despite relations and intermarriage with the West, followed the Byzantine model, promoting its archbishop to

➤ GOD-ANOINTED KINGS AND EMPERORS

The apex of Christological ruler ideology in the West occurred during the Ottonian empire. The portrait on the frontispiece of the *Aachen Evangelary* from shortly before 1000 depicts Otto III (r. 983–1002) crowned by the hand of God. Otto is enthroned and holds the royal insignia, symmetrical and forward-facing like a Roman Caesar. Two archbishops and two warriors, representing sacred and secular power, stand in the bottom register, while two crowned kings above them bow in subservience to the emperor. Tellus, the earth, crouches below the throne, personifying the empire's enormity.

In addition to this imperial imagery, the miniature includes religious iconography, essentially re-creating the traditional scene of Christ in majesty with Otto in Christ's place. The almond-shaped halo around the emperor, the gold background, and the four beasts of the Apocalypse (symbols for the evangelists) are all attributes of Christ. The beasts hold a white drapery across Otto's body that acts as the veil of heaven, placing the emperor partly in paradise and partly on earth. Otto's head and chest are emphasized by the veil and the intersection of his halo with the one surrounding God's hand. This was precisely where the ruler was anointed in the Ottonian coronation liturgy: head, breast, shoulders, and brachial joints. The image portrays a highly unusual glorification of a living emperor, exalting the ability of divine unction to create Christ's representative on earth.

patriarch in order to perform imperial unction. Eastern protocol was carefully followed, since Stephen's aim was to conquer Byzantium. He cultivated an expensive relationship with the monasteries of Mount Athos, hoping—mistakenly—that this revered Orthodox center would provide him with sufficient divine favor.

Bulgaria's allegiances vacillated between the West and East. The early empire of the tenth century followed the Byzantine liturgy, whereas a second empire under the Asenevetsi dynasty was established in 1187. In 1202 the ruler Karlojan (r. 1197–1207) requested imperial coronation and establishment of a Bulgarian patriarchate from Pope Innocent III (r. 1198–1216). Against

these wishes, the pope's legate crowned Karlojan as only a king and created a mere primature (a primate-archbishopric rather than a patriarchate) for the Bulgarian Church. Kalojan, undeterred, wrote to thank the pope for his imperial coronation. Bulgarian allegiance then quickly returned to the East, when the Byzantine emperor, Alexius III (r. 1195–1203), offered to recognize Kalojan's title as emperor.

The large Georgian Bagratid kingdom arose in the late eleventh century by defeating the same Seljuk Turks who captured the Byzantine emperor in 1071. Accordingly, the Georgian monarchs saw themselves as equals to the rulers of Constantinople and used the title *basilius*.

Queen Tamar the Great (r. 1184–1212) was sovereign during Georgia's height and was hailed "by the will of our Lord, King of Kings and Queen of Queens."

Armenia was separated by mountains and its Monophysite interpretation of Christianity (which held that Christ had a single solely divine nature instead of dual human and divine natures). Levon the Great (r. 1198/1199–1219), founder of the Cilician kingdom (1198–1375) in southern Anatolia, petitioned the Western emperor Henry VI (r. 1190–1197) for the Crown in exchange for his acceptance of Catholic doctrine. Levon's coronation by the papal legate in 1199 featured a translation of the Latin rite with unction by the Armenian *catholicos*, who was the primate, or chief archbishop, of the Armenian Church. Several months later, the Byzantine emperor (again, Alexius III) sent a competing diadem from Constantinople, but Armenia remained Catholic until the Turkish conquest of 1375.

While Russia's real attempts at autonomy began in the sixteenth century, Byzantine ideologies of rule were introduced by Vladimir of Kiev (r. 980–1015) and Metropolitan Alexis (r. 1354–1378), who, in particular, argued for the powerful Russian Church's subjugation to the secular ruler. These ideas reached new extremes with the development of the imperial tsar (caesar) in the later Middle Ages. The tsar was considered fully above all worldly laws, anointed and guided by God in all his actions. He dictated all political, judicial, moral, and religious decisions for his subjects and demanded their "joyful obedience" in return.

Far from these empires was another Christian realm under the rule of a divinely anointed king: Ethiopia, a mountainous redoubt amid Muslim Northeast Africa. In the fourth century King Ezana established Christianity there, claiming a heaven-sent right to rule.

After centuries of struggle with Islam, a Christian kingdom was reestablished in 1270 by Yekuno Amlak (r. 1270–1285), who founded a dynastic line, the Solomonids, that endured into the twentieth century. Yekuno claimed descent from King Solomon and the Queen of Sheba and employed this heritage as the basis for his divine rule. The legal code of Ethiopia, the *Fetba nagast*, or "Laws of the Kings," provided a scriptural

basis for the sacred right of the rulers, employing particularly Paul's epistle to the Romans. Paramount among the royal duties was protection of the endangered faith. Kings engaged in many religious tasks, such as translating theological tracts into Ge'ez (the ancient language of Ethiopia), founding monasteries, and establishing an altar at the Church of the Holy Sepulcher in Jerusalem. Yekuno was a devout patron, inscribing on his rock-hewn chapel in Roha: "By the grace of God, I, King Yekuno Amlak, after I had come to the throne by the will of God, built this church."

Royal power reached an apex under Zara Yaqob (r. 1434–1468). His elaborate court ceremonies demonstrate an extreme interpretation of divine kingship. When riding throughout his realm, Zara Yaqob was preceded by chained lions and officers with whips and drawn swords. Looking directly at the king was prohibited and punishable by immediate execution.

Marriage Law of the Latin Church

From 1000 to 1500 CE, marriage law in the Latin West was comprised of the canons, or ecclesias-

tical rules, of the Roman Church that were drawn from numerous sources: biblical prescriptions; the decretals, or legal decisions, of popes; laws enacted in ecumenical councils; the decrees of regional synods; and the opinions of the Church's Fathers (its ancient teachers) and its academic canon lawyers. At the same time, canonical justice regarding marriage and the family closely followed Roman civil law and its procedures but also showed flexibility by adapting certain rules to Germanic customs.

In medieval Western Europe, secular courts in general deferred litigations involving the validity of a marriage and the legitimacy of children to ecclesiastical courts. These two issues linked marriage not only to a family's properties and privileges but also to alimony, custody, child support, and other related matters. In practice, a secular court would adjudicate a dispute over inheritance and other relevant issues only after an ecclesiastical court established the legitimacy of a marriage or an heir. This separation of jurisdiction gave the Roman Church exclusive authority in legislating and enforcing laws of marriage and the family.

The Church did not officially declare marriage a sacrament until the Council of Trent (1545–1563). However, for centuries many theologians and canon lawyers had discussed the idea of sacred marriage, and many of them had accepted the image created by St. Augustine (354–430) that construed marriage as a symbol of the union of Christ and the Church. Although theologians often considered earthly marriage as an unfortunate necessity with the single purpose of procreation, church authorities were, in general, quite tolerant of literary and philosophical speculations about true love between married couples and the pleasures of marital sex. The main reason the Catholic Church held firmly to the idea of chastity as being a superior state to that of carnal marriage was to rein in fornication, concubinage, and other forms of sexual misconduct among its clergy. Of course, this constant reinforcement of the notion of chastity did have a profound impact on shaping popular perceptions of marriage and sexuality.

Medieval canon law did not formally establish a minimum age for legal marriage, leaving issues of underage marriages and parental con-

Illuminated marriage contract, French, fourteenth century. (Krause, Johansen/Archivo Iconografico, SA/Corbis)

sent to be regulated by local customs. Canon law also discouraged marriage across religions, and some canonical courts imposed severe sanctions against those who married adherents of other religions. Such a policy brought increasing pains to Catholic believers during the late medieval period, when crusades against heresy and the madness of witch-hunting victimized religious dissidents and jeopardized their families.

"Free will to consent" was one of the most controversial subjects speculated on by canon lawyers. Most believed that consent to marriage by both male and female partners was crucial because marriage involved a permanent commitment. However, while advocating the idea that no one is to be married to another save by free will, legal texts offered a tremendous amount of argument over its judicial ramifications based on hypotheticals, but none offered a straightforward definition of free will. It was Pope Alexander III

➤ INDISSOLUBLE MARRIAGE

After Abelard, a twelfth-century theologian and schoolmaster of Paris, was castrated by ruffians sent by the angry uncle of his wife Heloise, Abelard and Heloise took vows to submit themselves to the monastic life. In one of their correspondences, Abelard wrote to Heloise about their indissoluble marriage and durable love:

“Come too, my inseparable companion, and join me in thanksgiving, you who were made my partner both in guilt and in grace. For the Lord is not unmindful also of your own salvation, indeed he has you much in mind, for by a kind of holy presage of his name he marked you out to be especially his when he named you Heloise, after his own name, Elohim [Hebrew for ‘God’]. In his mercy, I say, he intended to provide for two people in one, the two whom the devil sought to destroy in one; since a short while before this happening he had bound us together by the indispensable bond of the marriage sacrament.”

Betty Radice, trans. *The Letters of Abelard and Heloise* (Harmondsworth, UK: Penguin, 1974), 194.

(r. 1159–1181), himself a canon lawyer, who ruled that a bridegroom would be declared to have consented to a marriage by free will unless he had acted in response to a level of fear sufficient to move a constant, or steadfast, man. Afterward, juristic interpretation of the rule of moving a constant man became the focus of new canonical debate. Most canon lawyers preferred a restrictive interpretation that suggested that the rule should be narrowly applied to annulling a coercive marriage initiated by rape or other kinds of excessive violence if such a marriage did not endure a long enough time period to appear as a normal marriage.

As was the case in Roman civil law, for an ecclesiastical court to declare a marriage valid, a couple must have exchanged pledges of mutual consent in the present tense. If a couple exchanged pledges of mutual consent in the future tense, such a marriage would be declared valid

only after sexual consummation was ascertained. Ecclesiastical courts did not automatically reject a marriage constituted on one or more conditional pledges of mutual consent. Rather, they would first examine whether the conditions were realistic, reasonable, and moral before rendering a judgment. Ecclesiastical judges, while applying those rules to settle a dispute over the validity of a marriage, would often adjust canonical technicalities to regional and local customs, since most marriages of the popular masses were clandestinely (privately and without the presence of a priest) contracted in rural Europe. In late medieval church courts, many marriage disputes involved various sorts of precontracts, namely that someone who claimed to have had a prior marriage to one of the partners challenged an ongoing marriage. If the court established that a pledge of mutual consent was legal in the earlier marriage, though clandestinely done, the later one would be declared annulled.

Under the leadership of Pope Innocent III (r. 1198–1216), the Fourth Lateran Council (1215) enacted canons to either reaffirm or reform the judicial rules governing and regulating marriage. One canon forbade clandestine marriage by requiring that a marriage be publicly contracted in the Church, with a suitable time being fixed beforehand within which impediments of any kind would be adduced. However, this law had limited impact on encouraging people to give up privately contracted marriages until the sixteenth-century Age of Reformation. Another canon enacted in the council redefined prohibitions against marriage by reducing the impediment of marriage by consanguinity (blood relationship) and affinity (relationship by marriage) from the seventh to the fourth degree. However, this canon did not stop people from contracting marriages within the forbidden degree of third cousins, nor did it discourage marriages to the siblings or close blood relatives of deceased spouses. Moreover, church authorities never strictly enforced laws against consanguinity and affinity in royal and aristocratic marriages. For various political reasons, the papacy usually granted dispensations for such marriages to be blessed.

Since canonical theory defined a marriage as a permanent commitment instead of an ongoing process, it insisted that a marriage, once legiti-

mately contracted, could never be dissolved. Therefore, legal divorce did not exist in ecclesiastical jurisdiction. A marriage could be declared annulled (namely, it was judged never to have been a legitimate marriage) only if the judge should find a flaw in the process of free consent to a union or discover an impediment to such a union, such as a prohibited degree of consanguinity. One consequence of this legal practice was the victimization of children. Once a marriage was annulled, the union was rendered to have never existed, and the children born to that union became illegitimate and lost the legal right to inheritance.

From the mid-eleventh century onward, church authorities repeatedly announced and enforced laws against clerical marriage and all other forms of sexual encounter by the clergy by announcing that women involved in such relationships were concubines and the children born from those relationships illegitimate. Canonical authorities also implemented rules against and imposed severe penalties for certain sexual practices such as fornication, adultery, bigamy, rape, prostitution, incest, homosexual sex, and even masturbation, which the Church viewed as sinful behaviors against the procreative purpose of sexual intercourse. Some of the lists of sins in certain areas and during certain time periods actually ranked masturbation as worse than rape and incest, which were believed to serve the procreation purpose even if they were wrong and criminal. Those rules became deadly when they were used abusively to try, convict, and punish heretics and witches in late medieval Europe.

The Church's absolute stand against polygamy and clerical incontinence and its view that a second marriage was legitimate only if the previous one was legally ended by death or annulment led to some interesting attitudes and legal rules. For example, a twice-widowed man or a man whose deceased wife was a widow was banned from the priesthood, and second marriages should omit a formal blessing by a priest.

In short, marriage law, family law, and laws regulating sexual conduct were interrelated in the medieval canon law of the Latin West and reflected the ideals and doctrines of the Church of Rome. In articulating the mission of the Fourth

Lateran Council of 1215, Innocent III announced that the purpose of those ideals and doctrines was "to eradicate vices and to plant virtues, to correct faults and to reform morals, to remove heresies and to strengthen faith, to settle discord and to establish peace, to get rid of oppression and to foster liberty."

Mexica (Aztec) Marriage Customs

Our knowledge of the marriage customs of the Mexica, or Aztecs, is based on the observations of early Spanish missionaries and travelers. Although there were variations in their accounts, these records collectively provide a fairly good overview of how Mexica society dealt with marriage.

A young woman married between the ages of 11 and 18, and it was expected that she would be a virgin. A young man would be married by the age of about 22 unless he intended to become a priest. Because the Mexica were brought up to honor and obey their parents without question (and even adults treated their parents with great deference), marriage rarely took place without parental consent. A young man who married without the consent of his parents and kinsfolk was regarded as ungrateful and ill-bred. Indeed, parents' kin usually chose a son's or daughter's marriage partner.

Mexica civilization was organized on a clan basis, and usually marriage partners were sought

► TYING THE KNOT

In the mid-sixteenth century, the Franciscan priest Bernardino de Sahagún and his native assistants recorded the oral testimonies of elders regarding every imaginable aspect of Aztec beliefs and customs. The result was the 12-volume *General History of the Things of New Spain* (known also as the *Florentine Codex*). The following excerpt describes one of the many rituals involved in the marriage ceremony.

“[W]hen they had gone to take her to the home of the man, then they placed her before the hearth. Then they also placed her bridegroom there before the hearth. And when the two were together, they placed the woman to the left, and they placed the man to the right of the woman. And the mother of the man then went to give gifts to her daughter-in-law. She placed the shift on her. . . . And the mother of the woman then also went to give gifts. She tied a cape on [the man]. . . . And the elderly matchmakers then tied them together. They took the corner of the man’s cape; also they drew up the woman’s shift; then they tied these together.”

—Alfred J. Andrea

from outside the parents’ own clan. When the parents had chosen a partner, the priests would be consulted to ensure that the couple’s birthdates were harmonious and to determine the lucky or unlucky days for holding the ceremony. Once the priests had given a favorable report, the man’s parents would get his tutors to release him from his education so that he could marry. Two older women would then approach the girl’s father, with gifts so that they would be welcomed, and ask for his daughter in marriage. By convention he would refuse, several times. Each time they made the request, they offered more-valuable gifts. Eventually the father would agree to seek the approval of the girl’s clan, and if they agreed the most auspicious day for the wedding would be established by the priests.

The wedding began around midday on the chosen day with a banquet at the girl’s home. Presents were given to the bride by married women; this was followed by the bathing of the bride. Her hair was washed and arranged, and she was dressed in a heavily embroidered dress with the legs and arms decorated with red feathers. Older members of the groom’s family now visited her and welcomed her to their family, and at nightfall they escorted the bride to her new home. She was carried there by an older woman and escorted by her friends and relatives and numerous well-wishers in a procession lighted by flaming torches.

The wedding ceremony was performed by the family hearth. The couple sat side by side on mats, and the groom’s mother presented the bride

with new clothes. The bride's mother gave a similar present to the groom. The two women who arranged the marriage on behalf of the groom's family then tied the cloaks of the bride and groom together, after which the couple shared a maize cake. The couple then sat and listened to orations and instructions from their elders about married life and about their obligations. Before the marriage was consummated the couple separated for four days, during which they fasted and prayed. The marriage was then consummated on a bed of piled mats and feathers with pieces of jade interleaved, the latter to ensure that the couple managed to have many children. After the consummation, the couple went for a ritual bath and a blessing and purification from the priest.

Family and Social Structure in Mississippian Cultures

"Mississippian" is a name utilized by archaeologists to describe the material remains of maize farmers who lived along the Mississippi River and its tributaries between about 1000 and 1650 CE. Many Mississippians constructed earthen mounds, building on a long history of mound building in the present-day eastern United States extending back several thousand years. Scholars often divide Mississippian cultures into two major groups: Middle and Upper Mississippian. Middle Mississippian mound centers were often located along major river floodplains, such as the region of Saint Louis, Missouri. In contrast, Upper Mississippian villages were generally located in prairie patches in the northern portion of the U.S. Midwest. This distinction appears to correspond to a degree of maize dependency,

which was lower for Upper Mississippians than neighboring Middle Mississippians.

A variety of economic and social factors led to the development of Mississippian cultures from local predecessors, and connections with Mesoamerica have long been drawn. However, except for maize and a few other domesticated plants, which diffused from Mesoamerica through the present-day U.S. Southwest, no other significant influences on these cultures have been clearly demonstrated.

Mississippian social organization focused on the economic and political integration of regional populations through rituals focused on fertility and warfare. Mississippian societies are often described as tribes or chiefdoms, chiefdoms being ranked societies expressed in funerary rituals and settlement hierarchies. Mississippian communities varied greatly in size and complexity, the largest of which are considered by some researchers to be emergent states. These typological constructs (tribes, chiefdoms, states), however, mask much variation, particularly transitional points along the continuum of social complexity and particular historical trajectories. Cahokia, outside present-day East St. Louis, Illinois, was the largest and most complex mound center and may have played a key role in the Mississippianization of the eastern United States through migration and trade.

The Mississippian family was one based on lineal descent, with multiple generations of kin inhabiting neighboring households that shared activity areas such as storage features, cemeteries, and ritual structures. Production of food and crafts occurred predominantly at the household level. Residential architecture was variable, but many houses were constructed of earth and wood and had grass-covered roofs. Lineages were often ranked vis-à-vis each other, the most powerful of which were leaders within the settlements.

The largest mound in a settlement was usually a platform on which a leader's residence was situated. Smaller mounds ringing the plaza often contained residences of other important family heads. Construction of platform mounds occurred in multiple stages, suggesting the regular reconstitution of the authority of ruling families. Trade for exotic artifacts interred with these

► SUNWATCH VILLAGE

The SunWatch Village site, occupied between 1150 and 1450 CE. (Robert A. Cook)

SunWatch village is an Upper Mississippian site of a few hundred people that was occupied between 1150 and 1450. The site is located along the upper portion of the Great Miami River south of Dayton, Ohio, in an area that was a pocket prairie during occupation. A circular stockade enclosed houses arranged around a large cedar post and plaza. Burials and storage pits are located between the houses and the plaza. Houses were constructed of earth, wood, and prairie grass. Residential units consisted of individual houses and associated burial and pit features linked together into extended family groups of three or four houses each. These may have been corporate clans, with members in other villages. The village leader, a 35-year-old male with a lightning whelk shell ornament, was buried in the western part of the site near a tall red cedar house that was likely his residence as well as a communal structure, marked off by closer proximity to the center pole and by positions of key solar alignments and burial groups. This individual rose to power during a time of contact with Middle Mississippians, late in the occupation of the village. This interaction occurred during a time of marked environmental and social change in Middle and Upper Mississippian societies.

SunWatch is a National Historic Landmark owned and operated by the Dayton Society of Natural History. Each year more than 20,000 people from throughout the United States and various other countries visit the partially reconstructed village and the Heilman-Kettering interpretive center.

—Robert Cook

individuals fueled in part the leaders' growing prominence. These individuals—usually male—orchestrated large gatherings involving feasting, sacrifice, and likely the telling of important myths. The diet of these high-status individuals sometimes involved more than average meat consumption, and there is some evidence that choice cuts, which served as tribute, were processed in small, somewhat distant communities prior to travel to the mound centers. It is clear that leaders wielded considerable ideological power, but it is less clear how much of an impact this had on the economy, such as control over craft production and tribute extraction. Whatever power a leader held was regularly contested, particularly during times of crop failure and warfare.

Sacrifices of retainers or servants have been documented in association with the burials of important leaders. Charnel houses, used to prepare bodies for burial, have also been found in a variety of settlements. The focus on ancestor veneration in public ceremonies has deep roots in the eastern United States extending back several millennia.

Relationships between Middle and Upper Mississippian groups were complex. Early researchers frequently invoked migration scenarios to account for the origin of Upper Mississippian groups, namely that Upper Mississippians descended from Middle Mississippians adapting to different environments. Subsequent research, however, has shown that Upper Mississippians shared many traditions with local populations as well as being influenced by Middle Mississippian culture. Thus, there is now disagreement as to the significance of Middle Mississippian influences on Upper Mississippian developments. We know that tribes often form in relation to more complex societies such as chiefdoms and states, and this phenomenon partially helps to explain Upper Mississippian origins. For example, at SunWatch, Middle Mississippian contact occurred simultaneously with the settlement's development of ranked lineages and a village leader.

Chiefs and Commoners in Oceania

Although most typical of Polynesia, societies known as complex chiefdoms existed throughout Oceania. While much of Melanesia was occupied by tribal peoples without chiefs and much of Micronesia was occupied by people living in simple chiefdoms, complex chiefdoms existed in all three areas of Oceania. Chiefdoms differ from other types of societies in being composed of at least two ranks of people—chiefs and commoners—who occupy those statuses for life. In complex chiefdoms there may be additional

WHAT HAPPENED TO THE STATUES OF RAPA NUI (EASTER ISLAND)?

Shortly after the Polynesian settlement of Rapa Nui (Easter Island) around 350 CE, the land was divided into districts headed by the paramount chief and each of his sons. Construction of huge monolithic statues (*moai*) so characteristic of the island began about the year 700. Moai are thought to represent the deified ancestors of chiefs and faced inland so that their *mana* could protect the population. Statue building reached its peak about 1100 and continued for five more centuries.

The moai were probably commissioned by individuals or families. At inland quarries stone carvers roughed out a rectangular slab of volcanic rock. Next the distinctive features of the statues, including long sloping noses and prominent chins, were carved. While the average height of a moai was 13 feet (4 meters), some were as tall as 70 feet (20 meters). The statues were hauled using wooden sleds or rollers to the coast, where they were erected.

By about 1500, the population of Easter Island expanded beyond the carrying capacity of the land, resulting in deforestation, soil deprivation, and the inability to produce enough food. Conflict among chiefly districts, mainly between those on the higher-ranking west side of the island and those on the lower-ranking east side, resulted in the toppling of moai and a halt to the building of new ones. Gradually religious practices based on the moai were replaced by the Birdman Cult, which sought to restore peace through a system that

Moai figure on Easter Island. (Corel)

rotated annual leadership from chiefly district to chiefly district.

—Charlotte Neely

ranks, such as priests, navigators, and artisans. Chiefs themselves may be ranked into paramount chiefs, district chiefs, village chiefs, and so on. Complex chiefdoms are also typically characterized by the construction of large public works such as temples.

Three main factors typically came into play in determining whether a person was from a chiefly or commoner family: inherited *mana*, being a first-born rather than a later-born child, and being male rather than female. Mana was a powerful spiritual force present to some degree in all animate and inanimate objects. Chiefs were believed to have more inherited mana than commoners because they could trace their genealogy back to prominent gods and goddesses. While both chiefs and commoners could acquire additional mana through their accomplishments, such as learning how to be a navigator or training to become a priest, chiefs always possessed more total mana. Within both chiefly and commoner families, first-born children had more rank than their later-born siblings. Chiefs were typically the first-born child of a first-born child going back through a line of first-borns to the god from whom the family traced its genealogy. While not always the case, males typically had more rank than females.

Although commoners did the actual work of farming, fishing, tending animals, building boats and houses, making bark cloth, producing important crafts, and so on, the ultimate economic success of a group was attributed to the mana of its chief, who was seen as a kind of demigod. The political and spiritual harmony of a group was also attributed to a chief's mana. If enough unfortunate events occurred, however, the chief might be thought to lack the mana he was supposed to possess. The gods could withdraw a chief's mana for reasons understood only by the gods. Such an occurrence created a situation in which latter-born siblings of the chief or, theoretically, even a commoner with great achieved mana could rise to a chiefly position.

To preserve their mana, chiefs had to observe many taboos that restricted their freedoms. Typically a chief could only minimally interact with those of lesser rank, who were required not to touch him, to bow down in a chief's presence, and to avoid using or touching any posses-

sion of the chief. In Tahiti chiefs were carried in litters so that their feet would not touch the ground walked on by commoners. A chief often wore distinctive clothing that designated his rank. In some cases only a chief's sister had enough rank and mana to become his wife. A chief's wife was often guarded day and night until she gave birth so that no one could question the legitimacy of the chief's first-born.

Slavery in the World

Slavery, or the involuntary subjugation of one human being to another that normally included exploitation of labor, existed in all civilizations on the European, Asian, American, and African continents between 1000 and 1500. Most religions of the world, including Christianity, Judaism, and Islam, accepted slavery, and few questioned its existence. Men, women, and children became slaves as the result of war, kidnapping, legal judgment, and poverty. One striking characteristic of slavery between 1000 and 1500 is the religious and ethnic diversity of slaves because traders and owners did not single out one racial group for enslavement. The birth of the Atlantic slave trade by 1500, however, initiated a highly racialized form of human bondage.

Between 1000 and 1500, warfare was the major means through which people were enslaved, inasmuch as conquering armies captured groups of people, used them as laborers, or sold them in slave markets. Slave traders also conducted raids to gain captives whom they sold to merchants, individuals, or overland caravan routes. In Africa, slavery was part of various tribal social structures. Although harsh treatment and work practices existed, most slaves captured through tribal warfare were integrated into the tribes and families that owned them and were

treated accordingly. Poverty forced people into slavery as well. For example, in twelfth-century India, persons sold themselves or family members into slavery to ensure their survival during economic hardships. The Delhi sultanate also accepted slaves in place of cash, as revenue, and enslaved people who resisted the sultan's authority and refused to pay taxes. In thirteenth-century Angkor, Cambodia, individuals gave slaves to particular temples as philanthropic endowments to demonstrate their devotion to a specific god or to fulfill tax obligations.

Buddhists, Muslims, Jews, and Christians considered those who did not espouse their faith to be infidels (and often uncivilized unbelievers as well) and often justified their enslavement on this basis alone. But justification of the enslavement of "the other" also went beyond religious grounds. For example, rice farmers in thirteenth-century Southeast Asia considered nomads of the uplands as savages, organized raids on the mountain tribes, and used or sold their captives as slaves. Although Christians and Muslims alike believed that it was generally wrong to enslave coreligionists, during both the crusades in the Levant and the lengthy battle for control over the Iberian Peninsula, military antagonists considered each other as a source of slaves, and this included believers in one's own religion who happened to be fighting on the wrong side. During the age of the crusades, the Roman Church even threatened enslavement of any Christian selling or carrying strategic war materials to Muslims. Indeed, enslavement was legal punishment for serious crimes imposed on coreligionists by Muslims and Christians alike.

Slave traders and owners did not single out one particular race or ethnic group for the purpose of enslavement, but prejudicial stereotypes shaped the usage of slaves. Muslims, for example, preferred Turks and Circassians as slave soldiers (mamluks) for their alleged military talents, Indians as guards for their trustworthiness, and black Africans as laborers for their endurance.

The trade in human beings expanded across Europe, Africa, and Asia between 1000 and 1500. As a result of early Islamic expansion, Muslim slave traders initially bought and sold slaves from Egypt, North Africa, Central Asia, India, and Spain. They also learned about the Egyptian prac-

tice of enslaving black Africans and used trans-Saharan caravan routes from the Sahel, or savanna region, of West Africa, Bornu in central Africa, and Nubia (present-day Sudan) in northeast Africa to bring black Africans and Berbers to slave markets in Morocco, Tunisia, Libya, and Egypt. Arab traders who controlled the slave trade in eastern and central Africa from Cairo used the Nile River Valley to transport slaves to Mediterranean slave markets or for export across the Red Sea. Along Africa's Swahili, or East, Coast, another large slave trade existed. Arab traders bought Africans in close cooperation with local tribal chiefs who supplied the human cargo through tribal warfare or raids or from within the tribe. Traders then sold slaves via routes across the Indian Ocean to the Persian Gulf, India, and wealthy families in twelfth-century Guangzhou (Canton), China. Slavery existed in India for millennia before the arrival of the Muslims, but between 1000 and 1500 Muslim rulers increased and expanded the regional slave trade to Central and East Asian markets. Sunni Muslims sold Shia from Iran, and Iranians bought Hindu slaves in Lahore (present-day Pakistan) or Kabul (present-day Afghanistan).

The Mediterranean slave trade connected southern Europe, the Black Sea, western Asia, and northern Africa in a complex exchange of human beings. Genoese merchants traded slaves from central and eastern Europe over land to France and Spain or through the Crimea to the Middle East. They purchased slaves from Central Asia and sold them in Cyprus, Venice, and Genoa. Muslim traders supplied markets in the southern and eastern Mediterranean with slaves they raided or bought from Turkish and Mongol tribes in Central Asia and with Circassian slaves from the Caucasus region. Through slaves transported over land across the Sahara, these Muslim traders also familiarized Europeans with African slavery.

Slaves, wherever found, were largely laborers. They tended livestock, produced pottery, and dug canals. Male slaves did heavy manual labor in mines or agriculture. In the Arab world slaves usually did not work in large-scale agricultural production, but in Bahrain slaves dove for pearls, and in Basra they labored in date plantations. Rulers benefited from slavery by hiring

➤ SUGAR AND SLAVES IN THE MEDITERRANEAN AND ATLANTIC

During the crusades, European Christians discovered sugarcane in the Levant, and on Cyprus (in the eastern Mediterranean) they encountered slaves working in sugarcane fields. Crusaders brought sugarcane cultivation to Sicily, Corsica, and southern Spain, where the rapid rise in taste for sugar contributed to its large-scale production on plantations. The fourteenth-century Great Plague, however, had reduced the labor supply, and sugar producers quickly adopted as a solution the labor system of slavery that they had encountered on Cyprus. Genoese and Venetian slave traders sold slaves from the Balkans, the Black Sea, and Africa to these sugar producers. Consequently, by the early fifteenth century slavery in the Mediterranean was intricately linked to sugar production. Commercial production of sugarcane contributed to the preservation of slavery as a cheap labor source in the Mediterranean. Although the trade in black Africans gradually increased in the Mediterranean, it was not yet the most important one. That would change during the late fifteenth century when sailors in the employment of Portugal and Spain began to explore the Atlantic Ocean.

Explorers sailing along the West African coast discovered and claimed the Azores, Madeira, Canary, and Cape Verde Islands. Portuguese and Spanish settlers transplanted plantation-style sugar production from the Mediterranean to these

islands and used conquered indigenous people as their labor force. Continuously growing demand for sugar required increased and improved production and a larger labor supply. As natives could no longer fulfill the labor demands, Portuguese and Spanish sugar producers utilized the already well-established trade network with nearby West Africa to tap into the existing source of slavery already familiar to them. Although amounting to no more than 2,000 slaves per year by 1500, sustained demand for improvements in commercial sugar production and location contributed to increased reliance upon enslaved labor from West Africa. When sailors in the employment of Spain and Portugal explored the Caribbean and South America during the late fifteenth and early sixteenth centuries, they brought with them the knowledge of plantation-style sugar production. The Portuguese were the first to transplant it to their possession in the New World, in Brazil, in 1544. Once the labor supply of native peoples dwindled due to high death rates, Spanish and Portuguese settlers quickly adopted the labor system already familiar to them through the East Atlantic Islands, black African slavery. The emphasis of the slave trade now shifted from the Mediterranean to the Atlantic connecting the European, African, and American continents.

—Petra DeWitt

out state-owned or municipal slaves to private individuals. Militaries used slaves as professional soldiers. Wealthy families sought slaves as domestic servants, cooks, gardeners, seamstresses, wet nurses, and watchmen. Noble men bought female slaves as concubines, and both female and male slaves were sent to brothels. Although Islamic law forbade bodily mutilation, eunuchs, or enslaved castrated men who received their operation before arriving at their destinations, were in high demand as guards for harems.

Tax records for Genoa indicate that nearly 8 percent of urban trading center populations on the Italian peninsula were slaves. In the slave markets in the northern Mediterranean world, women outnumbered men because Europeans sought slaves primarily for domestic work. In

fourteenth- and fifteenth-century Florence, Italy, 10 percent of all female servants and wet nurses were slaves.

Laws regulating the rights of slaves varied by region. In fourteenth-century Naples, slaves could own property and sue their masters. Although female slaves could not protect themselves from sexual advances by their male owners, laws in Ragusa and Siena in present-day Italy required that fathers adopt children gained through such unions or provide for their financial well-being. Male slaves in Mediterranean or Islamic commercial centers were usually educated, acted as agents for their owners, and had the opportunity to accumulate property. In Sicily, Greek Orthodox Christian slaves could gain freedom six years after conversion to Latin Christianity. In

the Jewish world, slaves who converted to their owner's religion did not necessarily gain freedom, but a manumitted slave who had converted to Judaism held full membership privileges in the religious community including the right to marry. Under Islamic law, slave marriages with consent of the master were valid, and it was possible for slave women who gave birth to her master's son to gain her freedom. The son born to the slave woman could inherit his father's property if the master's wife had no sons.

Slaves could rise to prominence, but individual success stories such as Balban, a Turk of the Ilbari tribe who was sold into slavery in India in 1232 and rose from personal attendant to sultan in 1265, were rare. Professional slave soldiers, by contrast, could gain wealth, freedom, and power. Mamluks, or white slave soldiers of Turkish or Circassian origin, rose in the ranks to become officers and commanders of Islamic armies. Obedience to the master translated to loyalty to the commander, and once a mamluk gained his freedom for service, the former slave could become a monarch, such as the Mamluk sultans who reigned in Egypt (1250–1517), Syria (1260–1516), and India (1206–1290).

Owning slaves was a sign of status in all societies. After the Black Death epidemic of the mid-fourteenth century, slaves in the Mediterranean world were no longer just a sign of wealth but an economic necessity. Agricultural slavery in southern Europe began to grow at the same time with the advent of sugarcane production and required an increasing number of male slaves. Spanish and Portuguese rulers also entered the slave trade in the thirteenth and fourteenth centuries, as their military reconquest weakened the stronghold of Muslims over the Iberian Peninsula. With the shift of empires, the slave trade in the western Mediterranean changed from Muslims selling Christians and other nonbelievers to buyers in the Islamic and Christian worlds to Christians trading Muslims in Córdoba (Spain), Narbonne (southern France), and Genoa.

Although slavery continued to exist throughout the world after 1500, the institution witnessed important changes. The Mediterranean

slave market changed as the rise of the Ottoman empire in the eastern Mediterranean slowed the flow of slaves from Central Asia and Turks diminished the importance of Arab merchants. Between 1000 and 1500, northern Europeans largely ended the enslavement of fellow Europeans in favor of serfdom and a free peasantry. By contrast, southern Europeans perpetuated slavery in the Mediterranean and through exploration contributed to the establishment, maintenance, or expansion of slavery in new possessions abroad. Successful production of sugarcane for export in the Mediterranean and on various Atlantic islands, such as São Thome off the African coast, encouraged southern Europeans to use African slaves more widely. Spaniards and Portuguese consequently imposed racial purity laws during the 1490s and no longer divided society along religious lines but instead divided it along racial lines. As early as 1518, Charles I (V) of Spain initiated the large-scale transportation of slaves from West Africa to its possessions in the Americas because indigenous people were already dying out. In 1544, the Portuguese set up plantation-style sugar production and slavery in Brazil. Settlers on the North American continent would transform slavery into a race-specific labor system that uprooted millions of Africans.

■ Introduction: Medieval Identities—Confronting the Other

In 1352 Abu Abdallah Muhammad ibn Battuta, who had already spent 26 years traveling throughout much of Afro-Eurasia, undertook one last journey. This final adventure took him from his home in Morocco, across the Sahara, to the empire of Mali in the grasslands of western Africa, a land that Islamic geographers characterized as *bilad al-sudan*, the “Land of the Blacks.” Upon his return he narrated his almost three decades of experiences and impressions to a professional writer, who fashioned them into a *Rihla*, a book of travels.

When discussing the people of Mali, who were, like Ibn Battuta, Sunni Muslims, the traveler displayed a mixture of admiration and scorn bordering on disgust. Whereas Ibn Battuta praised the Blacks for their well-run state and honesty, as well as their piety, he disapproved of the freedoms enjoyed by their women and especially their shocking lack of modesty. He was also disgusted by their eating unclean animals, such as carrion, dogs, and donkeys.

A century and a half later, Christopher Columbus composed a letter shortly before arriving back in the Iberian Peninsula in April 1493. In that letter, which was meant for wide circulation, he described the people whom he had encountered in the “Indies.” He reported that he had found no “human monstrosities,” meaning dog-headed persons or people with no heads and eyes set in their chests or similar “monsters,” as several millennia of Greco-Roman, Arab, and European geography had led him and most others to expect in lands yet to be explored. Rather, he found them “well-formed” but timorous in the extreme, quite innocent, and ripe for conversion to Roman Christianity. Those who remained “idolaters” would be prime candidates for slavery.

Such combinations of sentiments were common to many accounts by persons across Afro-Eurasia who, during these five centuries of dramatically increased travel and interchange, met and had dealings with persons of other ethnicities and cultures. Ethnocentrism was rampant, and religious affiliation was often a major

factor in coloring a person’s view of a stranger. But religion was not always a determining factor.

The early-thirteenth-century Mongols were generally tolerant of all religions and those who practiced them but had a deep contempt for urban dwellers. Moreover, perhaps in reaction to traditional Chinese attitudes and policies toward the “barbarian” peoples along the Middle Kingdom’s frontiers, the Mongols harbored a special dislike and distrust of the Chinese. When finally all of China had been conquered and the Yuan dynasty was established, native Chinese who had been subjects of the Southern Song dynasty were placed at the bottom of a four-part class system, well below the Mongols, who naturally stood at the top of the hierarchy, and also beneath the Mongols’ many non-Chinese allies and civil servants, such as Tibetans, Persians, and Uighurs. They even were ranked beneath the Chinese and sinicized non-Chinese who had been subjects of the alien Jin empire that had occupied northern China until 1234 and had become comfortable with Mongol ways because of their proximity to Mongolia and early submission to Mongol rule. Moreover, most Mongol khans in China took great pains to preserve Mongol identity and to prevent their people from being assimilated into Chinese culture.

On their part, many Chinese elites—the literati—retired from public life, refusing to serve Mongol masters. That, however, was not the whole story. There was a pro-Chinese faction within the ruling family that was constantly at odds with those Mongols who sought to maintain the purity of the traditional ways of the steppe. Several of the later Yuan emperors even emulated Chinese ways. To counter such acculturation, one Mongol chancellor, acting in the name of the last of the Yuan emperors, Toghon Temur (r. 1333–1368), established a law forbidding the Chinese from learning Mongolian. In the end, hated Mongol rule was overthrown in 1368 by a nativist revolution.

The narratives of Ibn Battuta and Columbus and the experiences of Chinese and Mongols during the Yuan era combine to illustrate the

complex nature of identity during these five centuries. In a world far more parochial than the twenty-first century, ethnocentrism and religious bias were undoubtedly far more deeply rooted than today, and the alien other was certainly less easily embraced and accepted. Notwithstanding, sufficient anecdotal evidence exists to suggest that there was also room for finding common ground and even for cultural interchange and adaptation.

—Alfred J. Andrea

Was There a Bilad al-Sudan?

The era from 1000 to 1500 CE was one of significant changes in the savanna and forest regions of West Africa. One key component of the social, economic, and political developments going on at the time was the expansion of contact with the predominantly Muslim populations of North Africa. While archaeology, linguistic analysis, and oral histories provide important information about the region during this period, the writings of Islamic geographers, who were among the most learned scholars of their time, are another important source of information. For example, our best description of the political system of Ancient Ghana comes from the late-eleventh-century Spanish Muslim geographer Abu Ubaydallah Al-Bakri. These sources must be used cautiously, however, because they also fail to distinguish between the believable and the outrageously fanciful. Ibn al-Fiqih, for example, wrote that gold grew in the soil and was plucked up each day “like carrots.”

Another troublesome aspect of these early geographic sources was their frequent description of the regions south of the Sahara such as the *Bilad al-Sudan*, Arabic for “Land of the Blacks.” Similarly, the peoples of the savanna and forest regions of West Africa were frequently referred to as “the Sudan.” This is notable in that it is one of the earliest classifications of a people in what would now be considered overtly racial terms. Such terminology is problematic in that it tends to lump a great diversity of African ethnic groups into a single category. This is not unlike the tendency of some modern books to make sweeping generalizations about “Black Africa,”

➤ AL-BAKRI, *THE BOOK OF ROUTES AND REALMS* (1067/1068)

“The city of Ghana consists of two towns situated on a plain. One of these towns, which is inhabited by Muslims, is large and possesses twelve mosques. . . . Around the king’s town are domed buildings and groves and thickets where the sorcerers of these people, men in charge of the religious cult, live. In them too are their idols and the tombs of their kings. The king’s interpreters, the official in charge of his treasury and the majority of his ministers are Muslims. Among the people who follow the king’s religion only he and his heir apparent (who is the son of his sister) may wear sewn clothes. All the other people wear robes of cotton, silk, or brocade, according to their means. . . . [The king] sits in audience or to hear grievances against officials in a domed pavilion around which stand ten horses covered with gold-embroidered materials. Behind the king stand ten pages holding shields and swords decorated with gold, and on his right are the sons of the [vassal] kings of his country, wearing splendid garments and their hair plaited with gold. The governor of the city sits on the ground before the king and around him are ministers seated likewise.”

something that makes scholars of Africa very uneasy.

Notably, many of these early Arabic scholars also described the Sudan in what today would be considered racist ways. The Sudan are often characterized as ugly, violent, dishonest, and sexually immoral. In part, these negative descriptions of the peoples of West Africa may be attributed to the fact that what is unfamiliar is often feared, demonized, or just dismissed as inferior. Furthermore, since Islam at the time permitted the enslavement of so-called pagans, there was a need to dehumanize those who might be enslaved. Such characterizations were also apparent during the era of slavery in the Americas.

By around 1500, however, the term “Bilad al-Sudan” was being used less often. Rather, as savanna populations converted to Islam, the region was characterized as just another part of the Dar al-Islam (Abode of Peace). This switch in terminology reflects the changing attitudes of Muslim scholars as they came to know more about West Africa and the people who lived there.

So, was there a Bilad al-Sudan? The answer is, sort of. Such a place existed in the minds of Islamic scholars and in the books they wrote, and the term lives on in the name of the modern nation of Sudan. In the final analysis, however, this is another example of the fact that the way people identify and name a region or culture often tells us more about the people who are doing the naming than about what they are trying to describe with a convenient tag.

The Copts

For the Copts, the largest Christian community of Egypt, the years between 1000 and 1500 represented a period in which they struggled to maintain a coherent sense of identity while increasingly relinquishing their influence in public life, having long since resigned themselves to their status as a demographic minority within a permanent Islamic polity. Even so, their fate as a community proved to be inextricably tied to wider Egyptian society during these centuries. Sociopolitical stability for the region often brought them the same; times of crisis—whether famine, crusades, or fiscal difficulties—proved to be dangerous for their collective success and safety. Their role in Egyptian society was also far from negligible. Many successive Muslim rulers took interest in their fortunes, for better or worse, and the Copts themselves managed to find meaning and renewal in the most unexpected times and places of this difficult age.

From 969 to 1171 Egypt was ruled by a small sect of Ismaili Shia known as the Fatimids. From

the time it captured Egypt from its Sunni Abbasid governor, this dynasty maintained an unusually amicable relationship with its non-Muslim constituency, largely to bolster public support from any community other than the Sunni majority. It was by no means a period without its dark days for the Copts, however: the mercurial caliph al-Hakim (r. 996–1021), for example, ordered in 1009 a harsh enforcement of lapsed restrictions on non-Muslims throughout his lands. Copts were ordered to wear only certain clothing styles and colors, wear heavy wooden crosses around the neck, and ride only donkeys (i.e., only Muslims could ride horses). This pressure eventually culminated in the caliph’s order of the destruction of many churches and monasteries around the country, as well as the conversion of masses of Christians under duress. With equal unpredictability, al-Hakim then repealed his orders, paid for and in some cases personally monitored the reconstruction of many of the targeted sacred structures, and even made the unusual move of granting permission for many of the forced converts to Islam to revert to Coptic Christianity. It is also worth noting that all of Egypt, particular greater Cairo, suffered under his rule. His occasional social crackdowns, for example, were reported to include a ban on women leaving their homes without caliphal permission and an order to slaughter every dog in the city.

The reign of al-Hakim and the benign approach of the Fatimid state during much of the rest of its history were representative of just how varied the experience of the Copts throughout the period of medieval Islamic rule could be, and the ensuing years of the Ayyubid dynasty (1171–1250) proved just as unpredictable. Its founder, the famed general and reconqueror of Jerusalem Salah al-Din (Saladin), began his time in office by removing all non-Muslims from government posts, the Copts chief among them, but he quickly reinstated them once the point of his authority had been made. The crusader attacks of the period, meanwhile, also led to the some of the harshest conditions of the era for the Coptic community. As successive waves of invasions by the Franks turned to the Nile Delta beginning in 1218, suspicion toward Egyptian Christians led the otherwise benign ruler al-Adil

(r. 1207–1218) to place pressure on Copts and other local Christians. This included his order to destroy the Church of St. Mark in Alexandria, a site dear to the heart of Coptic Orthodoxy in tradition if not practice by then, for the evangelist Mark was believed to have been Alexandria's first Christian bishop. Ironically, the Copts suffered greatly during the so-called Fifth Crusade (1217–1221) when large numbers of them died through starvation and combat wounds due to crusader sieges.

The Copts managed to overcome periodic Ayyubid pressures in the thirteenth century, and they enjoyed a brief cultural renaissance in the 1220s and 1230s during which time a weak (and largely vacant) patriarchate contributed to their channeling resources, energy, clerical interest, and lay attention to artistic and intellectual pursuits. This included unique and colorful iconographic projects at the monastery of St. Anthony by the Red Sea (including images of Roman equestrian saints such as St. Mercurius, who are depicted donning the distinct gear of thirteenth-century Turkish cavalry) and that of the Syrians in Wadi al-Natrun, as well as the popularization of Arabic-Coptic grammars to revitalize knowledge of the Coptic language, which had fallen completely from popular use and significantly from liturgical use by that time.

By the time the Mamluk dynasty (1250–1517) seized control of Egypt and turned its attention to decades of resistance to the last crusades, the remnants of the crusader states, and the imminent Mongol threat to the north, the Coptic mini-renaissance had largely faded back into status quo. In fact, it was under the Mamluks that the Copts faced their most devastating communal losses to repression and subsequent conversion. The ruling classes of the Bahri Mamluks (r. 1250–1382) were entirely of Central Asian origin and had little experience with or interest in local non-Muslims. Thus, when harsh economic conditions struck Egypt in the mid-fourteenth century and unrest on the part of the Muslim majority turned in part to violence against their non-Muslim neighbors, the Mamluk rulers were decidedly slow to act upon their official obligations to protect their *dhimmi* (tolerated non-Muslim) subjects. It is now widely accepted by historians that when the dust settled, the Copts

➤ BADR AL-JAMALI

The Fatimid era maintained a general atmosphere of tolerance toward the Copts, sometimes leading to surprising encounters. For example, a half century of political disarray followed the death of al-Hakim in 1021, and only the intervention of an imported Armenian army under the leadership of the general and vizier Badr al-Jamali (r. 1074–1094) restored stable authority to the dynasty. The general was a convert from Armenian Christianity, and apart from the military and political prestige that he retained until his death, he also affected the religious balance of the country for a time. Thousands of Armenian Christians flooded into the country behind his army and settled in the vicinity of Greater Cairo, and he also demonstrated surprising respect for local Coptic traditions. The *History of the Patriarchs of the Egyptian Church* claims that in 1086 he personally convened a meeting with the Coptic patriarch and bishops in his palace garden after news reached him of deep divisions within the Church and there ordered them to return two weeks hence with a new compendium of canon, or church, law. The chronicle mentions that following the meeting, the general ordered the execution of a wayward layman who reportedly mocked and humiliated the patriarch, explaining that there was no excuse for disrespect of the successor of St. Mark. When the bishops returned with this collection of canons at the appointed time, Badr al-Jamali is reported to then have given a rather Christian-like sermon, explaining that he ordered the canons so that the Copts could be reminded of their own traditions and convicted by their guilty consciences of their need for unity in the process. His leadership, it appears, extended to spiritual as well as military and administrative affairs.

Ethnic-Cultural Diversity amid Religious Identity and Unity in Dar al-Islam

The Quran provides the basis for the unity of the *umma*, or Muslim community, that makes up Dar al-Islam (or lands of Islam under Islamic rule). Simultaneously, it supports ethnic, cultural, and linguistic diversity, as reflected in the passages "O, humankind! We . . . made you into nations and tribes so that you may know each other" (Sura 49:13) and "Among His signs are . . . the variations in your languages and your colors" (Sura 30:22).

Between 1000 and 1500 CE, Islam continued as the dominant religion throughout most of the realms stretching from far western India northward into Central Asia and across Persia, the Arab Middle East, and Berber North Africa, as well as portions of the Iberian Peninsula (until 1492). During these 500 years, Islam also made vigorous inroads into central and eastern India, the coastal regions of Swahili Africa and Africa's western Sudan, the western and northern regions of interior China, and China's southern coastal area, with some Muslim scholars suggesting penetration as far east as Korea by the seventh or eighth century. Additionally, Islam was moving vigorously into the coastal areas of Southeast Asia. Both among the various peoples of these already-established domains of Dar al-Islam and among newly Islamicized regions, the deli-

cate balance between ethnic and cultural diversity and religious identity and unity manifested itself.

After initial advances into Azerbaijan and surrounding regions, Islam penetrated into the more northern areas of the Caucasus in the eleventh and twelfth centuries. Among the myriad Indo-European, Indo-Iranian, and Turkic-based local dialects there, Arabic arose to replace such former trade languages as Aramaic, Pahlavi, and Albanian, thus producing a shift in cultural expression among the region's newly converted peoples, with Arabic serving thereafter as the primary literary and religious language. But here too a unique form of Caucasian Islamic devotion grew, which proved culturally distinct from the Bulgarian, Turkic Central Asian, Persian, Arab Middle Eastern, and other forms of Islam surrounding them.

It was likewise from out of newly Islamicized Turkic Central Asian groups in this period that four of the greatest Muslim writers arose to lay the foundations for a strong Turkic linguistic and cultural-based tradition within Islam. In the heartland of the Qaraqanid khanate (or Karakanid: 845–1212), Yusuf Balasaguni produced his famous *Kutadgu Bilig (Wisdom of Royal Glory)* in his own Turkic dialect in 1069, with its strong allusions to pre-Islamic Turkic cultural and political traditions. Mahmud Kashgari, a Turkic Muslim from Kashgar in the eastern reaches of the Qaraqanid realm, composed the *Diwan lughat al-Turk (Dictionary of Turkic Languages)* in 1076, affirming the high value of the Turkic mother tongues. Among the Qipchaq (Kipchak) Turks, Kozha Akhmet Yasawi, founder of the Yasawi Sufi Order of Central Asia, bequeathed his *Diwani Khikmet (Book of Wisdom)* in the mid-twelfth century as he spread Sufi Islamic devotion among the predominantly nomadic Turks of the Qipchaq steppe. Several centuries later the Naqshbandian Sufi writer Ali Shar Nawai (1441–1501), who earned the title "Shakespeare of Central Asia" from later admiring generations, produced one of the greatest arrays of Turkic literature yet to appear, all written in his native Chagatay dialect, the precursor of modern Uzbek.

Meanwhile, the newly converted Seljuk and Ghaznavid Turks, who had migrated into and taken over reign of the Arabo-Persian Middle East,

had both embraced and even promoted Persian, along with Arabic, as a genuine Muslim language. Nonetheless, it was the earlier Samanid Persian state (819–999) in the heart of Central Asia that played the most significant role in supporting the development of a linguistically and culturally distinct Persian form of Islamic devotion. Under the Samanids, Firdowsi (934–1026) wrote the *Shahnama* (*Book of Kings*) in Persian with its strong allusions to pre-Islamic Persian cultural and political traditions. Included within the great Persian Islamic literary heritage that followed was the impressive commentary of Mibudi and Jalaladin Rumi's (1207–1273) masterpiece, the *Mathnaw* (or *Masnawi: Spiritual Couplets*), which aimed to lift out the inner spiritual meaning of the Quran.

Developments of a uniquely Indian-laced Islamic identity began to take clearer shape nearly two centuries after the initial Ghaznavid invasion of the Punjab and northwest India, which occurred in the early eleventh century. Building upon the initial Ghaznavid conquest, Turko-Afghan military units of mamluks (slave soldiers) took over the Ghaznavid domains and extended their reach deeper into Indian territory late in the twelfth century. By the early fourteenth century they had moved into the heartland of central India. After an initial two centuries or so of religious persecution of indigenous Indian traditions, relations between Muslims and Hindus began to achieve a greater degree of coexistence, yielding a cross-pollination of Arabo-Turko-Persian Islamic and Indian art and architecture as well as poetry and other forms of literature. This was in large part based in a cross-influencing and even merging of mystic spiritual paths, particularly the Sufi Islamic and Bhakti Hindu forms of affective, or emotional, devotion.

Farther east, traditional Islamic and Chinese calligraphy as well as other art forms interacted to develop a unique synthesis, while Chinese Muslim participation in all levels of Chinese life was evidenced. Expressions of a distinctly Chinese form of Muslim devotion eventually inspired Wang Taiyu to produce an explanation of Islam in largely Confucian terms in the seventeenth century.

The first records of Dar al-Islam's penetration into Southeast Asia appear in the thirteenth

➤ THE KURDS

The Kurds—culturally, linguistically, and even religiously—have long been one of the most singular people of the Islamic Middle East. They have for centuries inhabited Kurdistan (“Land of the Kurds”), though today their land is an unrecognized nation divided up among four other nations. Kurdistan is predominated by the high Taurus and Zagros mountain ranges intermixed with plains stretching from present-day western Turkey across northern Iraq and Iran. Kurds also reside in Syria.

Kurdish is distantly related to Persian, of which there are at least three dialects: Kurmanji among the Kurds of Turkey, Behdini in Iraq, and Sorani in Iraq and Iran. Kurds have generally identified themselves as Sunni Muslims, though historically there has been and remains a significant Shia and even Christian presence among them, not to mention the various Sufi orders, most notably the Naqshbandi, which was formed in the late fourteenth century, and the Mevlavi, or Whirling Dervishes, which traces its origins to thirteenth-century Konya and the mystical poet Jalauddin al-Rumi (1207–1273). Medieval Kurds also had their Jewish minorities. Yazidism, a religion with origins shrouded in mystery but generally considered an amalgam of Zoroastrian, Jewish, Christian, Manichean, and Islamic elements, has historically been another minor faith among the Kurds.

The most prominent figure of medieval Kurdish history was Sultan Salah ad-Din Yusuf ibn Ayyub (1138–1193), known in the West as Saladin, a champion of Sunni orthodoxy and founder of the Ayyubid dynasty that ruled Egypt from 1174 to 1250 and Syria from 1176 to 1260.

—R. Charles Weller

century, with Sufi preachers from the Arabian Peninsula, as well as the Indian subcontinent, playing the predominant role in its spread. They translated classic Arabic and Persian works into Malay, aiding significantly in the development of Malay as a “Muslim language” and, with it, a distinctly Malay form of Islamic devotion. Islam also found its way to the Javanese islands around the fifteenth century, though the Muslim presence in Java at that time seems mainly to have consisted of Chinese who migrated there. But

Persian traces are to be found as well, with both mixing with indigenous elements to give Javanese Islam its own unique ethnic-cultural blend.

In sub-Saharan Africa the influx of new African peoples into Dar al-Islam from the eleventh century onward brought with it still other ethnic-cultural forms of expression of the faith. Included among these new groups were the peoples of Ghana and Mali, as well as Songhai and Hausa. Within Mali the city of Timbuktu became a center of Islamic learning, contributing not only to the broader heritage of Dar al-Islam but also to the development of distinctly Black African forms of Islamic expression.

Amid this ethnic-cultural diversity within Dar al-Islam, the Arabic language continued to flourish as a primary base, helping to provide ongoing religious unity. Famous Muslim scholars of various ethnic-cultural as well as political heritages did their teaching and produced their greatest works in Arabic. These included the Turkic scholar al-Farabi (870–950) from the southern region of present-day Kazakhstan; Ibn Sina (980–1037), whose roots were in the Turko-Persian heartland of Bukhara in what is now Uzbekistan; the Muslim traveler al-Biruni (973–1048) from the northwest regions of that same modern state; the Persian Sufi scholar al-Ghazali (1058–1111); Ibn Rushd (1126–1198), residing in Andalusian Cordova; the Persian courtier and historian Rashid ad-Din (1247–1318); and the Moroccan world traveler Ibn Battuta (1304–1377).

Ibn Battuta's life and adventures highlight another way in which a common Islamic religious identity and unity were fostered in this postclassical period. His extensive travels throughout Dar al-Islam were made successful in large part by the Muslim heritage that he and his many ethnically, culturally, and politically diverse hosts shared. The same can be said of the travels in this period undertaken by al-Biruni and others.

The annual hajj, or pilgrimage, to Mecca made by thousands of Muslims each year also bears witness to the strong sense of religious identity and unity among Muslims. The hajj of the king of Mali, Mansa Musa, in 1324–1325 so captured the attention of the Muslim world that his journey is still recounted to this day as one of the most memorable in Islamic history.

Hindu and Muslim Cross-Fertilization in India

The 1,000-year history of Islam in India has often been marked by confrontation, antagonism, and even open warfare with indigenous Hinduism. Theologically, it would be difficult to find two religions more different. Yet in the Indian environment, different forms and attitudes developed, and Hinduism under challenge reacted and reshaped itself like an oyster that encounters a splinter.

Islam first reached India via Arab and Persian merchants who landed along the coast of the Arabian Sea during the seventh century and accepted Indian hospitality similar to that of their pre-Muslim predecessors. Unfortunately, the role of Muslims in the subcontinent best remembered is that of Arab conquerors in eighth-century Sind (in present-day Pakistan) and temple plunderers and iconoclastic destroyers, most famously the Turkic Mahmud of Ghazni in the eleventh century. Conquering bands of Muslim Turks and Afghans settled in as sultans of Delhi in 1205.

Alien warrior bands could not closely administer a widespread settled populace, so they began with a garrison state in which traditional local leaders continued in place, paid the taxes, and genuflected toward the seat of power in the fortified garrison. However, apartheid could not last; rude warriors from the hills needed missing

pieces of society: merchants, moneylenders, artisans, lawyers, clerks, accountants, and so on. In this way the new rulers' constant antagonism with the massed Hindus soon eased into an acceptance of them socially as *dhimmis* (tolerated unbelievers), however much Islamic theologians might object.

Within a short period, significant minorities of Indians had converted to Islam, mostly from lower castes, attracted by Muslim ideals of egalitarianism. Sufis had a major role in these conversions. These Muslim preachers and mystics went about singing of the glories of Allah and the promises of his Holy Quran. The devotion and compassion of the Sufis did more to build India's Muslim community than the political pressures of sultans or the formal prayer rituals of imams.

However, the vast majority of Hindus stayed true to their traditional faith and lifestyle. Many reacted by joining sects of the emotional bhakti (devotional Hindu) movement, shouting, singing, and perhaps even dancing in adoration of Krishna, Shiva, or some other personification of the godhead. Bhakti saints such as Chaitanya and Mirabai and poets such as Tulsidas put new fervor and zeal into their old faith.

By 1500 Islam had penetrated most of the South Asian subcontinent and created distinctive communities in the south as well as the north. If many Indian Muslims were poor peasants, many others were proud and powerful elites. Most Muslims of India, like most elsewhere, were Sunni, but there were notable Shia communities in Lucknow in the north, Bijapur in the south, and the trading ports of Gujarat and Sind in the northwest.

Separate communities of Hindus and Muslims usually found ways to get along. Only if some incident occurred or something upset the status quo might there be a communal quarrel or even a riot. Friendships might cross communal lines, but dining and marriage arrangements hardly ever crossed communal lines, despite fictional depictions of them.

Nonetheless, one can see the gradual development of a composite Hindustani culture. Well-to-do Hindus began secluding their wives and daughters as Muslims did. Muslim parents began arranging their children's marriages (or at least their engagements) in childhood. Hindus began appreciating the roast meat or vegetable dishes

➤ NAMDEV AND KABIR

The attractions of Islam presented a challenge to the older religions of South Asia. How could Hindu leaders combat the relatively simple, egalitarian, and dynamic preachings of Islam, especially the Muslim sufis? Some tried to strengthen the appeal of Hinduism through the bhakti, or devotional, approach, emphasizing personal ties to a specific aspect of the divine. An example is Namdev, a fourteenth-century poet-preacher who composed many hymns in the Marathi language of west-central India. His hope for salvation was Vishnu, whom he called "Vitthal" or "Vithoba." He was one of a series of bhakti saints who helped form the Maratha popular and regional identity.

Kabir (1440–1518) took a more radical turn. A Banares weaver of uncertain origin, Kabir scorned the use of priests, prayer rituals, and sacred texts. He asked, "What is a Hindu? What is a Turk? Both inhabit the same earth. One reads the Veda, and the other the Quran and the Khutba. . . . [B]oth are misled, none has found God." Caste distinctions and idol worship were frequent targets of his sharp wit. Being against sects, he refused to found one, but his followers, the Kabir-panthis, wrote down his songs and promulgated his ideas.

—Edwin Hirschmann

that the hill folk had brought into India (along with syrupy sweets), while the newcomers learned the creative use of robust spices. North Indian men began wearing trousers (i.e., pantaloons, pajamas, and jodhpurs) instead of wrap-arounds, such as the dhoti.

Hindustani music presents clearer evidence of how these peoples bridged the communal gap. Here the ragas (themes) and their variations, the tala rhythmic counts, and the moods show no earmarks of Hindu or Muslim. The kathak dance style of the North Indian courts is also used to present Hindu-based pieces. Monumental architecture might be Hindu or Muslim (i.e., Central Asian) in style, but not until Mughal times (of the early sixteenth century through the early nineteenth century) was there an adroit blending of the two.

The most intricate blending came in the field of language. The Muslim invaders, with their

capital at Delhi, picked up enough of the local dialect (called Khariboli) to communicate with area people in bazaar Hindustani or Zaaban-i-Urdu, the speech of the camp. The official language of administration was always Persian, as it was for refined literature. Not until the eighteenth century were there significant efforts to develop Urdu as a literary language. It used the Perso-Arabic script and borrowed abstract words from Persian. This made it largely a Muslim product and its use a source of Muslim pride.

Out in the *mufasssil* (grassroots), however, theological boundaries were sometimes lost. An anthropologist in the late twentieth century found a remote South Indian village where no Muslims lived, but a centuries-old grave with a Muslim name was regularly decorated and venerated by the villagers. Apparently, a wandering Sufi had settled there and attracted the villagers with his personality and his vision of the divine, and they did not associate him with “Hindu” or “Muslim,” if they even knew those names.

The Armenians in Late Medieval Society

From Flanders to China, the Armenians were an often-silent yet ubiquitous presence in late medieval life, maintaining a strong commercial profile and religious presence in the East and West before, during, and after the Pax Mongolica (ca. 1250–1368).

After the year 1100, Armenians were the dominant presence in two areas of southwestern Asia: Greater Armenia, their original homeland located in the mountainous Caucasus region between the Caspian Sea and the Euphrates River, and Lesser (or Cilician) Armenia in the

southeast corner of Anatolia (modern Asiatic Turkey), which migrants from Greater Armenia colonized in the second half of the eleventh century. In addition to these two Armenias, they established diaspora communities of merchants and artisans throughout much of the Afro-Eurasia, especially along its major trade routes. Despite their diffusion, Armenians resisted amalgamation into their host cultures because of their strong sense of ethnic identity; their distinctive Indo-European language, which had a rich tradition of secular and religious literature dating back to the early fifth century; and their Christian faith, based on an autonomous church that had separated from Constantinople and Rome around the mid-fifth century.

Armenia was recognized in the West as the first Christian state (the traditional date is 301), and the religious devotion of its people drew widespread respect despite doctrinal differences. Matthew Paris in his *Chronica Majora* (*Major Chronicles*) reported on some Armenian clergy visiting St. Ives in England in 1250: “These brethren were of most honest life and amazing abstinence, being always in prayer, with rugged, honest faces and beards. The one who died was their leader and master, George by name, and he is thought to have been a most holy man and a bishop; he now began to perform miracles.”

Initially, the violent disruptions occasioned by the first Mongol incursions of the early thirteenth century into historically Armenian territories sent Armenian monks, such as George and his brethren, to the West for help, but within a very short time they accepted the challenge of ministering to the Mongols. At the Mongol *ordos* (camps), Armenian clergy were welcomed at the highest levels since many of the Mongol leaders’ wives were Nestorian (Assyrian) Christians from birth. William of Rubruck, Franciscan envoy to the Mongols, noted with some envy in 1255 that the Armenians had a beautifully decorated church in Karakorum, the original Mongol capital, where the Great Khan’s wife often worshipped. With the arrival of Latin Christian missionaries in Central and East Asia, Armenian merchants living in far-flung colonies throughout the Middle East and China supported them spiritually and financially. As noted in the book *Christians in China before the Year 1550*, Fra Andreas da Perugia (An-

drew of Perugia), a Franciscan bishop in Mongol China, reported back to the West in 1326 from Zaitun (present-day Quanzhou): “[A] wealthy Armenian lady built a sufficiently beautiful and large church, which indeed, after it had been made a cathedral by the Archbishop, she gave of her own will while she was living, and left at death with adequate endowment.”

From the first years of the crusades, Armenians based in Cilicia forged military and trading partnerships with the crusader states and the Genoese and Venetian merchants who had now become a dominant factor in the eastern Mediterranean. Reciprocal trade agreements with the Italians in the Levant, which the Armenians cemented during the thirteenth century by intermarriage, gave rise to vibrant Armenian merchant colonies in Italy and other parts of Europe as well, particularly in Flanders under the dukes of Burgundy. Armenians are first mentioned in Bruges in the mid-fourteenth century, where they were given the right to sell carpets on the steps in front of St. Donation’s Church. In Italy they had flourishing colonies in Perugia, Bologna, Venice, and elsewhere. Several superb yet little-known Armenian illuminated manuscripts were produced in Italy: one from a scriptorium in Bologna dated to the 1260s presages the work of Cimabue and Duccio; another was produced in Perugia in 1331. Both are now in the Matenadaran Library in Yerevan, Armenia.

Ethnic Classification and Hierarchy during the Yuan Era

China’s Yuan dynasty (1279–1368) presided over an era known as China’s Mongol period because it was at this time that Mongol tribes, previously unified as an army under the leadership of Chinggis Khan (ca. 1162–1227), defeated the armies of China and extended their empire across eastern Asia. Khubilai Khan (1215–1294), a grandson of Chinggis Khan, became the first Mongol to rule over all of China with his defeat of the last Song emperor in 1279. While adapting to local customs was a key factor in how the Mongols attempted to integrate ethnically and culturally with the people of the places they had conquered, their success at integration is debatable.

Having lived in northern China during his childhood, Khubilai Khan was highly influenced by the teachings of Chinese Confucians and Buddhists. Even as his armies were driving south against the last remnants of Song resistance, Khubilai began construction in 1266 of his new capital, Dadu, at the site of present-day Beijing

➤ XU HENG AND THE PROMOTION OF CHINESE NEO-CONFUCIANISM UNDER MONGOL RULE

As ruler of China's Mongol period, Khubilai Khan attempted to appeal to a wide variety of ethnic, ideological, and religious groups. These included Tibetan and Chinese Buddhist monks, Neo-Confucian scholars, Muslim communities, and even Christians, such as Marco Polo. Khubilai made certain to appoint to his administration powerful Chinese scholars such as Xu Heng (1209–1281), a strong proponent of Neo-Confucian ideology who was known as one of the greatest thinkers of his time. Although Xu retired briefly from his position under Khubilai after a scandal in 1262, he returned and by 1267 had been appointed chancellor of education at the Imperial College. There he utilized the main books of Neo-Confucianism to teach many important figures, including Mongols and Central Asians. Through his teaching, Xu therefore found an avenue through which he could promote Neo-Confucian ideology within prominent political circles of the Yuan empire.

—Anna Hennessey

and claimed the title of Chinese emperor in 1271, giving his dynasty not a Mongol name but instead the Chinese name: Yuan. The title translates as “Great Originator,” a term that appears in the classic text the *Book of Changes*, where it refers to the “origins of the universe” or the “original creative force.”

Not only did Khubilai choose a Chinese dynastic name, but the Mongol ruler also built up his government by employing Chinese Neo-Confucian scholars as advisors who would educate Mongol officials about the cultural standards and practices of the Chinese. Important scholar-officials promoted Neo-Confucianism during China's Song dynasty (960–1279) and had already begun to revolutionize China's systems of education, philosophy, and government ahead of the Mongol invasions. By adopting this new philosophy and incorporating its precepts into their own form of government, the Mongols attempted to strengthen a growing intellectual trend that was Chinese and not Mongol at its root. Given

that internal conflicts arose within the administration, leading to events such as the disloyalty and subsequent execution in 1262 of the Chinese scholar-official Wang Wentong, the success of this attempt at political integration is not clear.

Prior to the Mongol invasions, the Chinese had sustained a long historical tradition of fighting off foreign invaders in their attempts at maintaining their own ethnic identity, an identity often termed “Han.” During his reign, Khubilai tried to construct a three- and later four-tiered ethnic hierarchy in China, placing Mongols at the top, Uighurs and other western and Central Asians next, followed by the northern Chinese and various sinicized peoples of the north, such as the Jurchen (Ruzhen), and lastly by the southern Chinese. The members of the two Chinese groups were excluded from a number of the most important civil offices. Thus, although the Mongols' embracement of a Neo-Confucian agenda within the sphere of politics may have played a part in the path to the intellectual reformation that many of these Chinese reformers themselves so desired, many Chinese later looked back on the Yuan era as a time of hated foreign domination.

Europeans or Christians? The Medieval European Sense of Self

“Europe” as the name of a continent is ancient, having been invented by Greek geographers who

conceived of a world that had three continents of equal size: Asia, Africa, and Europe. Nevertheless, the idea of Europe as we understand it today—a cultural entity that is the foundation stone of Western civilization—held no meaning for the Greeks or Romans, and this remained true throughout most of the so-called Middle Ages. In the oldest known European map of Europe, made by a twelfth-century monk of Saint-Omer in Flanders, Europe was only a place; there was still no notion of European civilization.

Those who lived in this land called Europe had a sense of unique self, but it was a self defined by religious identity. Between the sixth and sixteenth centuries CE—the period we now know as the Middle Ages—most of the people inhabiting the western end of the Eurasian land-mass came to identify themselves as Christians, especially as they came into increasing contact with non-Christians, and it was this sense of shared identity that drove them to acknowledge the spiritual authority of the pope and to embark on medieval Europe's greatest foreign adventure, the crusades. A notion of a common Christian identity, however, did not negate ethnic pride. By the twelfth century, French speakers in the lands around Paris, for example, thought of themselves as belonging to "Sweet France," which they assumed was culturally richer (and more Christian) than any other area of Christendom. A twelfth-century English historian and monk, William of Malmesbury, while celebrating the common effort of Western, or Latin, Christians in the First Crusade, also noted that its participants included Norwegians, who left behind their raw fish, and Scotsmen, who "abandoned their fellowship with lice." Negative stereotypes of other ethnicities that emerged from an inflated sense of one's own ethnic superiority were not a modern invention.

Toward the end of the Middle Ages, somewhere between the thirteenth and sixteenth centuries, the idea of Europe as more than just a geographic expression emerged and began to coincide with that of Christianity. Ironically, the word "European" (L. *Europaeus*) was first used to describe an inhabitant of the West by Aeneas Sylvius Piccolomini, the future Pope Pius II (r. 1458–1464), in a treatise he wrote calling for a new crusade against the Turks. In it Piccolomini

clearly identified Europe with what he referred to as the "Christian Republic."

In the following centuries as Europe was transformed by the Renaissance, the Reformation, the Scientific Revolution, and the Enlightenment, a self-conscious Christian identity receded in the minds of many intellectuals, and it became common for writers to think of themselves and their culture as "European." This was especially true as they became increasingly aware of the older and exceedingly sophisticated cultures of East and South Asia.

It must be kept in mind, however, that the vast majority of people remained poor and illiterate and that it was not until after the French Revolution, industrialization, and the age of colonialism, that is, well into the nineteenth century, that the average European had any sense that he or she was "European."

The Jew as Other in Catholic Europe

As the eleventh century dawned, Jews were fairly well assimilated into Western Europe's culture. However, as the power of the Latin Christian Church grew, pressure to convert increased, and they endured not only discrimination and persecution for imagined offenses but also physical violence and ultimately expulsion from England (1290), France (1394), Spain (1492), and Portugal (1497). In the eleventh and twelfth centuries, crusader armies, fired up against unbelievers, occasionally massacred Jews who refused Christian baptism, especially in the Rhineland. In the twelfth century, accusations of Jewish ritual murder of Christians and their desecration of churches and the Eucharistic host began. Yet despite discrimination, there were periods of peaceful coexistence between Christians and Jews, and some individuals were tolerant of and even protective toward this minority.

Badges and hats worn by Jews, from the *Bible Historiale* de Pierre Comestor, fourteenth century. The wearing of badges by Jews was ordered by Pope Innocent III at the Fourth Lateran Council in 1215. (Singer, Isadore, ed. *The Jewish Encyclopedia*, 1901)

Protected by Roman citizenship, Jews had settled in Gaul in late antiquity, moving northward along the major rivers and especially the Rhine, which were trade thoroughfares. They spoke the local forms of vernacular Latin, dressed as their Christian neighbors did, and engaged in a variety of occupations, including agriculture, viticulture, medicine, and various crafts. Valued for their long-distance trade connections and linguistic skills, they were protected by the Carolingian emperors Charlemagne (r. 768–814) and his son Louis the Pious (r. 814–840). Jewish merchants were exempt from certain tolls and duties on transported merchandise and enjoyed royal protection of their lives and property. Within the later German empire of the Ottonians and their Hohenstaufen successors, this favorable attitude became the basis of alliances, often defined in official charters, that made Jews dependent on the goodwill of local and imperial authorities. Speyer's bishop granted such a charter in 1080. Similar alliances were formed in England and France, although the French kings issued no formal charter. The alliances, however,

were unilateral, could be broken at any time, remained valid only while the Jews were useful, and subjected Jews to arbitrary taxation.

Although official papal policy from the reign of Pope Gregory I (r. 590–604) was to allow Jews to practice their religion and observe their own laws and customs, a policy that was reiterated by Calixtus II (r. 1119–24) in the papal bull *Sicut Judeis* and promulgated into canon, or church, law in the *Decretals* of Pope Gregory IX (r. 1227–1241), the Western Roman, or Latin, Church continued to assert its authority over Jews. Of particular ecclesiastical concern was the prevention of both subservience of Christians to Jews and any social interaction and intermarriage between the two groups as well as promotion of Jewish conversion to Christianity.

It was the failure of the Jews to convert that occasionally prompted massacres, most notably in the German cities of Worms, Mainz, Cologne, and Speyer in 1096 and in York, England, in 1190. When in 1095 Pope Urban II (r. 1088–1099) announced a military expedition to recover Jerusalem, the response, known as the First Crusade, was almost overwhelming. Large baronial armies and other less well-organized bands set off on the mission to the Holy Land. Some of the latter took the opportunity to attack nearby Jewish communities, including a group led by a certain Count Emicho. Marching through the Rhineland, these troops interpreted the pope's message by trying to force conversion on the so-called infidel enemies at home and attacking and even killing those who refused baptism. (And apparently many other Jews committed suicide and even killed their loved ones to avoid the profanation of forced baptism.) These attacks took place even when some Christian bishops attempted to shelter the Jews within the walls of their own palaces.

The myth of ritual murder of Christian children as a Jewish religious practice also developed in mid-twelfth-century England, where the alleged victims, especially William of Norwich (1144), Harold of Gloucester (1168), Robert of Bury St. Edmunds (1181), and Hugh of Lincoln (1255) were venerated as saints in cults sponsored by church authorities. Ritual murder and blood libel allegations, which sprang up on the continent as well, resulted in the deaths of in-

nocent Jews and further discrimination against them. Likewise, during the fourteenth-century onset of the Black Death, many Jewish communities were accused of having poisoned wells in order to kill Christians, and significant numbers of Jews were killed as a consequence.

The lives of French Jews varied regionally. Many lived peacefully, but there were conversion attempts and exiles. Philip II Augustus (r. 1180–1223) expelled them in 1182 to take control of their property, to stabilize his treasury, and to win popular support but recalled them in 1198. Jews expelled from England in 1290 migrated to France but soon, influenced by the Church's hardening attitude, were expelled again (1306) by Philip IV (r. 1285–1314). The decree was reversed in 1315 by Philip's son, Louis X (r. 1314–1316), but French Jews were finally expelled in 1394. Many migrated to Spain, where Jews were still tolerated.

Jews from Rouen first settled in England after the conquest in 1066, invited by William I (r. 1066–87). By 1189, there were 24 provincial Jewries, largely unmolested because as serfs of the king, they enjoyed his protection. English Jews engaged in large- and small-scale money lending. The king helped them collect unpaid debts, took possession of some loans himself, and arbitrarily taxed the Jews. Misunderstandings and the desire to destroy records of debt provoked violent attacks in England. In 1189, London Jews were attacked following the coronation of Richard I (r. 1189–1199) when prominent Jews attempted to enter Westminster and the banquet that followed the ceremony; other attacks followed elsewhere in England.

The York massacre of March 1190 followed attacks on the Jewries of Lynn, Stamford, and Bury St. Edmunds. To escape death, York Jews barricaded themselves in Clifford's Tower, part of the king's castle, and as in the Rhineland in 1096 many, facing starvation or forced baptism, killed their families and themselves. Survivors who emerged to accept baptism were murdered by the mob.

English kings taxed the Jews heavily in the following years. When Anglo-Jewish wealth diminished, the Jewish position grew more difficult. Their livelihood, money lending and pawn brokering, was abolished by royal legislation. In

➤ THE CHARTER OF THE JEWS OF SPEYER

In some European communities Jews were given special charters outlining their status within the community. Bishop Rudegar granted such a charter containing what he believed to be the most favorable conditions of any Jews in the German empire to the Jews of Speyer in the German Rhineland in 1080.

According to the charter, the Jews of Speyer were to live “in a place apart from the dwellings and association of the other inhabitants of the city; and that they may be protected from the attacks and violence of the mob, I [Bishop Rudegar] have surrounded their quarter with a wall.” They received “a piece of land of the church as a burial-ground,” and legal cases involving Jews were to be judged by the chief priest of the synagogue. Specific clauses gave the Jews “free right of changing gold and silver coins and of buying and selling everything they wish within their own walls and . . . throughout the whole city” and exemption from payment of the city toll for Jewish guests of Speyer's Jews. Especially noteworthy is the permission to “hire Christian nurses and Christian servants” because laws in many places forbade employment of Christians by Jews.

Rudegar Huozman, “Charter to the Jews of Speyer,” in *The Medieval Record: Sources of Medieval History*, ed. Alfred J. Andrea (Boston and New York: Houghton Mifflin, 1997), 255–257.

his 1275 Statute of the Jewry, Edward I (r. 1272–1307) forbade Jews to lend money for interest, urged them to make their living by other means, and required them to wear a cloth badge on their outer clothing identifying them as Jews as mandated by the Fourth Lateran Council in 1215. Finally, Edward expelled all Jews from England in 1290.

Expulsion from Western European countries pushed Jewish settlements steadily eastward. In Hungary, a small community of Jews was chartered by Bela IV in 1251 in the hope that more Jews would settle in Hungary and help to improve his country's economy. Hungarian Jews

were initially traders and craftsmen and later toll collectors, tax farmers, and moneylenders. Although expelled in 1360, Jews returned to Hungary in 1364. Poland was an attractive alternative to Hungary. The charter granted by Duke Boleslav of Kalisch in 1264 included provisions for a fair trial for Jews accused of blood libel and punishment for Christians who brought the charge falsely. The occupations of Polish Jews mirrored those of Hungary, but later Polish Jews became estate managers for aristocrats. Mongol invasions and epidemics of plague made Polish authorities more rather than less supportive of their Jewish communities.

By 1500 the Jews had been expelled from most major regions in Western Europe. Victims of expulsion from England, France, and Germany had moved either eastward or to the Iberian Peninsula. The 1492 expulsion from Spain sent Jewish refugees to Italy, the Netherlands, North Africa, and the Ottoman empire, but 150,000 Sephardic (Spanish) Jews moved to Portugal. Their residence in Portugal ended in expulsion in 1497, whereupon most migrated to various areas in the Ottoman-dominated Middle East, where many assumed leadership roles in old established Jewish communities.

Although sometimes welcomed and well treated, Jews continued to be identified as “the other,” restricted by law, urged to embrace Christianity, and forced to migrate, generally eastward.

Gerald of Wales and the Irish—An Ethnic Stereotype in Medieval Europe

The uncomplimentary portrayals of Ireland and the Irish in the twelfth-century writings of the Cambro-Norman (Welsh and Norman) ecclesiastic Gerald of Wales (Giraldus Cambrensis, ca. 1146–ca. 1223) held a dominant place in medieval and early modern Irish historiography, as well as in popular notions and depictions of Ireland. Although he was a consummate storyteller whose accounts are lively in style and colorful in content, Gerald's works have drawn substantial criticism because of blatant ethnic stereotyping, countless inaccuracies, and familial, political, and other prejudices and purposes. Yet for all their shortcomings, Gerald's accounts of the Irish provide a unique and contemporary perspective on the English conquest of Ireland as well as on various historical figures and events.

A member of the powerful Geraldine family who was much involved in the first Anglo-Norman conquest of Ireland (1170), Gerald was

A monk writing, late twelfth–early thirteenth century, from *Topographia Hibernica*, a work by Gerald of Wales. (HIP/Art Resource, NY)

one-quarter Welsh and three-quarters Norman and of noble stock in both instances.

Gerald was not only the first foreigner to compose a book about Ireland, but he alone of medieval chroniclers is known to have visited Ireland, not once but four times. He first went for a year during 1183–1184 to assist his relations in Ireland. Later in 1184 he was appointed court chaplain to Henry II of England (r. 1154–1189) and embarked for Ireland a second time at the king's behest. During Easter 1185, Gerald was part of the royal fleet that sailed for Waterford. He was handpicked to accompany Prince John, styled the “lord of Ireland,” on this second invasion of Ireland as both chaplain and adviser. Gerald remained in Ireland until the late spring of 1186.

During this second trip to Ireland Gerald began to work on two books: *Topographia Hibernica* (*The Topography of Ireland*), which he completed in 1188, and *Expugnatio Hibernica* (*The Conquest of Ireland*), completed in 1189. The former is divided into three parts that cover Ireland's topography and animal life, its wonders and miracles, and the Irish race and its history. The *Expugnatio* covers the history of the English conquests of and doings in Ireland from the exile of Diarmait mac Murchada in 1166 to the latest conquest of 1185–1186, followed by instructions on how the Irish were to be subdued and governed.

In his books Gerald describes the Irish as barbarians and inhospitable primitives who live like beasts, practice backward and immoral customs, and are Christians in name only. He further sees Norman civility, religious instruction, and Anglo-Norman social, legal, and political order as urgently needed remedies for the sinful and deplorable state of Ireland and its people.

The historian John O'Meara asserts that what Gerald saw firsthand was quite limited. Likewise, bias toward his own lineage and ethnicity influenced his accounts. Moreover, ethnic prejudice, his ecclesiastical reform agenda, and his association with the family and court of Henry II combined to justify, in his mind, the Anglo-Normans' legal and moral right to rule Ireland.

Gerald's unflattering conclusions continued to be a source for subsequent medieval and early

➤ EXCERPT FROM *THE HISTORY AND TOPOGRAPHY OF IRELAND*

“They are a wild and inhospitable people. They live on beasts only, and live like beasts. They have not progressed at all from the primitive habits of pastoral living. . . . This people then is a barbarous people . . . a filthy people, wallowing in vice. Of all peoples it is the least instructed in the rudiments of the Faith. They do not yet pay tithes or first fruits or contract marriages. They do not avoid incest. They do not attend God's church. . . . Moreover, above all other peoples they always practice treachery. When they give their word to anyone, they do not keep it. . . . You must be more afraid of their wile than their war; their friendship than their fire; their honey than their hemlock; their shrewdness than their soldiery; their betrayals than their battle lines; their specious friendship than their enmity despised. . . . These are their characteristics: they are neither strong in war, nor reliable in peace.”

—Katharine Olson

modern literary and historical depictions of the Irish. Contrariwise, Gerald's works were much criticized in seventeenth-century Irish broadsides and especially in the works of the early modern Irish historian Geoffrey Keating. In his condemnation of Gerald's accounts of Ireland, Keating wrote of their lasting influence: “Every one of the new Galls [Scottish Protestant immigrants] who writes on Ireland writes . . . in imitation of Cambrensis . . . because it is Cambrensis who is the bull of the herd for them in writing the false history of Ireland, wherefore they had no choice of guide.”

The Ethnic and Linguistic Divisions of the Americas on the Eve of the Columbian Exchange

Upon arrival on the coast of Mesoamerica, the Spaniards encountered a continent with an impressive ethnic and linguistic diversity, the product of thousands of years of cultural interaction among people living in diverse but interdependent ecological niches.

Our knowledge of the ethnic and linguistic division of the Americas comes principally from two types of sources. First, current linguistic distribution and ethnic affiliation have a direct relation to the situation just prior to contact, despite demographic and social changes that have occurred since the sixteenth century. Language, in fact, is a resilient feature of ethnic identity, because linguistic variations only occur very slowly over centuries and millennia. Linguists are therefore able to map and trace a family of languages over large expanses of territory and long periods of time. Today in countries such as Mexico, Guatemala, Ecuador, Peru, and Bolivia, millions of people continue to speak their pre-Conquest native tongues as a first language. The second source of information is historical documentation produced during the colonial period. Since the 1530s, missionaries of the Franciscan, Augustinian, Dominican, and Jesuit orders learned the native languages in order to preach to and convert the local populations. These efforts resulted in the creation of hundreds of dictionaries and grammars, compiled by these scholar-priests with the assistance of indigenous intellectuals. As early as 1536, for example, in Mexico City,

once capital of the Aztec empire, there was a college that trained indigenous nobility not only in Latin and Spanish grammar and rhetoric but also in Nahuatl (the language of the Aztecs), producing an intellectual elite responsible for an incredibly rich production of historical, literary, and religious texts throughout the colonial period.

On the other hand, Amerindian languages were and are primarily oral. That is, they did not have a consistent written tradition. As a result, the majority of these tongues, and their many local variations, have not been clearly documented. The work of linguists and anthropologists is still ongoing. Finally, before proceeding to a summary presentation of the different culture areas of the Americas and their linguistic and ethnic divisions, a word of caution must be added about the use of the term “ethnicity” itself. This is, in fact, a descriptive category coined and employed by anthropologists. More often than not, these categories were and are not recognized by the very people whose cultures and languages they claim to describe. While today we tend to consider language as a fundamental aspect of cultural affiliation, in pre-Columbian America major linguistic variations were found even within small geographic areas and did not constitute a marker of ethnic identity. On the other hand, people speaking closely related terms would consider themselves as totally distinct groups.

North America was host to more than 300 languages prior to European contact. Roughly 50 language families have been identified in North America. Families are languages that are thought to derive from a common ancestral language, although they need not be and in fact most of the time are not mutually intelligible. Each family can vary greatly on the number of distinct languages. One of the most extended families is the Algonquian-Ritwan, which stretches from present-day Labrador to the North Carolina coast and westward to Alberta. Languages of this family are also spoken in Illinois, Montana, and the Dakotas. The Athabaskan, or Na-Dene, family includes a large portion of the western Arctic region, including the Tlingit on the northwest coast and reaching into the Navajo and Apache regions of the present-day American Southwest. Another important group is the Kiowa-Tanoan family spo-

ken in the southern plains, the great basin area, and what is currently northern Mexico. The west coast, including the northwest coast and California, is the area with the greatest linguistic diversity. Finally, the Zuni of the Southwest are a linguistic example of what linguists call an “isolate,” that is, a language that is not part of any known language family. Nonetheless, their cultural and linguistic heritage shares many features with the other people of the region. Special ceremonial terms, for example, have been shown to be borrowed from different languages.

In Mesoamerica at the time of the Conquest, more than 200 languages were spoken. Of these, the most common were those of the Uto-Aztecan family, which also includes Nahuatl, the language of the Aztecs. Nahuatl also served as an international language that the Spaniards employed through translators after entering the region. Uto-Aztecan languages are found throughout Mesoamerica, from the northern desert stretches to present-day Honduras. On the other hand, the macrofamily of Mayan languages is found almost only in the so-called Maya area that includes the modern Yucatán and Chiapas in southern Mexico, Guatemala, Belize, and Honduras, with the exception of the Huastec, and is still spoken on the northern Gulf Coast. To this day, the greatest linguistic diversity is found among Otomanguean languages in the modern states of Puebla, Guerrero, and Oaxaca of southwestern Mexico.

Central America and northern South America were inhabited mostly by speakers of Chibcha and Arawakan languages, which are also found in the Amazon Basin, perhaps indicating that this is their place of origin.

South America is home to the most widely spoken indigenous language in the Americas: Quechua. Partly as a consequence of the Inca expansion in the fifteenth century, which included present-day Ecuador, Peru, parts of Bolivia, and northern Chile, Quechua is still spoken today by 8.5 million people. It is divided into several dialects (language variations that are still mutually intelligible) and shows many similarities with the Aymara language, spoken in the Bolivian highlands. The Quechua and Aymara people lived in very close proximity and interacted for thousands of years.

➤ MAYAN CULTURAL RESILIENCY

Even after the so-called Classic Maya collapse that brought about the end of the powerful city-states that dominated the southern lowlands (roughly corresponding to present-day Chiapas, Guatemala, and Honduras) by the end of the eighth century CE, Mayan civilization continued to thrive in other regions. While some important features of Classic Mayan civilization disappeared, the traditional political arrangement in city-states continued until the arrival of the Spaniards. The cult of rulership, based on ritual enactments of the king's divine powers, was typical of the Classical period but changed during the so-called Terminal Classical and Post-classical periods to the glorification of the kingdom as a whole and their patron gods. Mayan kingdoms of this period were large dominions that included several settlements and polities organized hierarchically. Allegiances achieved through marriages between different lineages constituted the most common basis of diplomatic relations. The large cities of Chichén Itzá and Mayapán ruled over large parts of the northern Yucatán throughout the Post-classical period. Located in the inland of this riverless territory, however, they heavily relied on maritime commerce that was carried out through the major ports located in the eastern coast of Yucatán. The major sites there were Tulum, Cozumel Island, and Santa Rita. In the Mayan Highlands, present-day Guatemala, major changes occurred in settlement patterns, with a shift from valley to hilltop settlements, reflecting increasing warfare activities.

—Alessia Frassani

Finally, another important language family is the so-called Guaraní, with over 5 million speakers in Paraguay today. It is estimated that about 400,000 lived in the area at the time of contact. Related languages are found in the Amazon Basin, northern Argentina, and parts of Bolivia.

■ Introduction: Gender Relations around the World—Does One Model Serve All?

The question posited in the subtitle of this essay is rhetorical. An even cursory glance at the entries under this topic reveals that gender relations and gender identities were not always and everywhere the same in the period 1000–1500 or in any other era of human history for that matter.

As we see, intersexed people, who had both female and male genitalia, were especially honored as “two spirit people” within many North American cultures, a phenomenon that seems unimaginable in many Afro-Eurasian cultures of the same time, such as China, Christian Europe, and Byzantium. It appears that this privileged status was accorded them because they were perceived as possessing the special and respected attributes, or spirits, of both women and men.

On the Great Asian Steppe, home to a number of Turco-Mongol nomadic cultures that were essentially similar in lifestyle, we find differentiated sex roles, to be sure. We also see, however, a rough-and-ready egalitarianism between the sexes, despite the fact that khans and other important male leaders could have 20 or more wives (each of whom, however, had her own ger, or yurt). We further have evidence of a number of women who exercised positions of at least persuasive authority. Given the primacy of honor accorded warriors in these cultures, this might seem surprising until we realize that the harsh conditions of steppe life gave value to the work and wisdom of each person. Moreover, a number of sources inform us that women rode the tough steppe horses as skillfully and courageously as

men, and this counted for quite a bit in a culture that centered on the horse.

Given its vast space and diversity of cultures, trying to sum up gender relations across Oceania in a single formula is imprudent. Clearly, gender-specific work roles were the norm, and men dominated in the area of religion. Overall, therefore, the social status of men was higher than that of women.

The same was generally true in the settled cultures of Afro-Eurasia, such as China, Japan, India, and the Christian and Islamic worlds. Although patriarchal traditions, notions of masculinity and a warrior ethos, scriptural mandates, legal constraints, and a variety of other factors placed men in a position of superiority within these complex cultures, extraordinary high-born women, such as Anna Comnena or Shajar al-Durr, could and did rise to positions of prominence. Evidence is lacking, but it is also quite likely that at the village, town, and even city levels, women who were peasants, artisans, shopkeepers, or merchants or who assisted their husbands, sons, or nephews in these occupations probably had a fair amount of autonomy and authority within their limited spheres.

We should also remember that gender roles were rarely positive or negative in any absolute sense. Women within most Hindu sects, for example, despite very real constraints on their lives by virtue of the traditions of dharmic law, had important religious roles to play in their households. When they performed these and all of their other gender-specific tasks well and selflessly,

they were considered to be *satis*, or virtuous women, who by their actions brought good karma on their families. In China the wife of a family's youngest son was little more than a servant, but if she and her husband lived long enough and had a sufficiently large and prosperous family of their own, she could rise to the honored position of matriarch, exercising over her daughters-in-law the same power once wielded over her in her mother-in-law's household.

These widespread cultures and "worlds" of Afro-Eurasia were also not monolithic in any sense of the term. While visiting the Islamic trading empire of Mali in sub-Saharan West Africa in the mid-fourteenth century, Ibn Battuta, a *qadi*, or Islamic jurist, from Morocco experienced the following incident:

"One day I went into the presence of Abu Muhammad. . . . In the courtyard of his house there was a canopied couch with a woman sitting on it conversing with a man seated. I said to him: 'Who is this woman?' He said: 'She is my wife.' I said: 'What connection has the man with her?' He replied: 'He is her friend.' I said to him: 'Do you acquiesce in this when you have lived in our country and become acquainted with the precepts of *Sharia* [Islamic religious law]?' He replied: 'The association of women with men is agreeable to us and a part of good conduct, to which no suspicion attaches. They are not like the women of your country.' I was astonished at his laxity. I left him, and did not return thereafter. He invited me several times but I did not accept."

Muslim Women—Veiled and Hidden?

Most available information regarding Islamic women that was composed between the years 1000 and 1500 deals exclusively with urban women, and all of it was written by men. Not-

As this thirteenth-century sculpture from eastern India demonstrates, Hindu society celebrated the ideal of sensual, romantic love between a woman and a man, despite the constraints placed on women. (Museum of Fine Arts, Boston, Massachusetts, USA/Keith McLeod Fund /The Bridgeman Art Library International)

withstanding, it is possible to discern a general picture of the status and lifestyles of Islamic women during these centuries.

In the context of Islam's spiritual and ethical teachings, men and women are equal before God. In everyday life, though, the situation has been quite different, and this was certainly the case in medieval Islam. To be sure, the activities and actions of Islamic women today and in the past have varied considerably depending on region and social status, and these variations have ranged substantially, from styles of Islamic dress (called *hijab*) to polygamy, seclusion, and marriage and divorce practices. Nevertheless, as already noted, it is possible to discern a general picture of the status and lifestyles of Islamic women, especially during the period 1000–1500.

In considering this issue, it is important to note that the era of the early Abbasid caliphate,

➤ SHAJAR AL-DURR

Besides involvement in religion and economics, women also took part in politics. The most famous example is Shajar al-Durr (String of Pearls).

Shajar al-Durr, a Turk who had been a slave to the Abbasid caliph in Baghdad, was given to the Egyptian sultan al-Salih Ayyub. Al-Salih fell in love with Shajar al-Durr and married her. In 1249 al-Salih died, and to protect the throne Shajar al-Durr kept the sultan's death a secret until his successor, Turan-shah, returned to Cairo. In the ten months between al-Salih's death and Turan-shah's arrival, she effectively ran the government at a time when Egypt was combating the crisis of a crusader invasion.

Turan-shah turned out to be unpopular and was murdered a short time later, probably at Shajar al-Durr's command, ending the Ayyubid dynasty's rule in Egypt (1171–1250). As a result, Shajar al-Durr reigned as sultana for almost three months, styling herself “Queen of the Muslims,” the only sultana in Islamic history. Under pressure to step aside because of her gender, she abdicated her title and married an officer of the imperial guard, Aybak (Aybeg), thereby establishing the Mamluk dynasty (1250–1517), which would rule Egypt and Syria for almost 300 years. There followed seven years of uneasy corule. Although no longer sultana, Shajar received diplomats, and coins were minted in both their names. In 1257 she arranged Aybak's assassination but was herself murdered three days later, reportedly tortured to death by slave women. Her tomb, which she had ordered constructed before her death, can still be seen in Cairo and is one of the best-surviving examples of thirteenth-century funerary architecture.

—April L. Najjaj

roughly 750 to 1000, was pivotal for the development of Islamic law (*sharia*) in regard to religious and social issues. Moreover, as the new religion spread out from the Arabian Peninsula, many non-Arab cultures were assimilated into the Islamic world, and a number of their practices regarding the treatment of women, most of which were products of male-centered societies, influenced this developing Islamic law and custom. Additionally, by the early tenth century

Islamic law was considered finalized, and the primary duty of judges (*qadis*) now was seen as upholding earlier rulings rather than developing original case-specific interpretations of the law. This meant that after the year 1000 Islamic women, especially in the so-called Middle East, were expected to live lives and follow customs that had been made law centuries earlier and that were a composite of a number of androcentric (male-centered) cultural traditions, many of which had roots that went back millennia.

Within this Islamic tradition, women were required to live under the guardianship of a male relative, whether father, husband, or son. Many women were active in the local economy but usually only within the limits allowed by society and sharia. Upper-class women did own property in their own right and sometimes created religious endowments called *waqfs* to provide housing, work, and religious instruction for poor women, widows, and orphans. Nevertheless, the amount of property these women owned and the income they derived from it seldom allowed for any woman to be self-sufficient. Among the lower classes, women were involved in textile production and served as shopkeepers, bakers, midwives, prostitutes, professional mourners, and singers, or they could enter the homes of the wealthy to sell food and luxury goods.

The typical design of houses in the medieval Islamic world was inward looking and emphasized family privacy. Domestic space was organized where windows were above street level, and doorways were offset from the outside entrance so that passersby could not see inside the residence. Such a design also allowed for greater seclusion for the women of the house. Houses could be large and could contain separate living quarters for several women (the *harems*, or area of female seclusion, privacy, and security). Throughout its history, Islam has strongly encouraged marriage for both sexes, and the marriage age for girls in the medieval period usually ranged between 12 and 17. Sharia allows a man to have as many as four wives but only if he can equally support and spend time with each wife; thus polygamy, while allowed, was usually beyond the financial or physical means of most men and was rarely found outside the ruling classes.

The orthodox view of women encouraged by the religious establishment was not the only perspective, however, for other groups within Islam tradition took several significantly different views. One group, the Kharijis, an Islamic sect that originated soon after the Prophet's death, preached and practiced an egalitarianism that went so far as to allow women to fight in battle, and a second group, the Qarmatis, a tenth-century Shia sect that also preached and practiced a rough-and-ready equality of all believers, banned polygamy and the veil. Both groups, however, as well as many other Islamic sects that deviated from mainstream practices, were persecuted out of existence. A third group, the Sufis, expressed a more mystical version of Islam and also challenged orthodox views on gender. Women were considered to be significant contributors to Sufi traditions, including one of the best-known early Sufis, Rabia al-Adawiyya (d. 801). Another was Fakhru-n Nisa, "The Glory of Women," a follower and close confidant of Jala-luddin al-Rumi, the great thirteenth-century Sufi mystic and poet of Konya. Unlike Kharijism and Qarmatism, Sufism has survived to the present day.

Toward the end of the medieval period, at least upper-class girls had increasing access to education but were usually taught informally at home by a male (or sometimes female) relative. For boys and girls, the basis of early education would have been religious instruction, but the close association between Islam and the Arabic language would have required reading and grammar skills, encouraging at least a basic level of literacy.

Womanhood in Early and Medieval Japan

The status and role of women in Japanese history has changed drastically through the ages. A woman-centered marriage system in ancient times is a strong indication that women had considerable political and religious influence in Japan's earliest centuries. Chinese chronicles from the third century CE provide vivid descriptions of a female ruler in Japan, Pimiko, who wielded considerable power. Likewise, Japan's earliest anthology of poetry, the eighth-century *Manyoshu* (*Collection of Ten Thousand Leaves*), has poems in which love marriages and great respect for women are the rule.

Women-centered marriages, where it was customary for the husband to join the family of his wife or to live separately and to visit his wife on certain nights, continued through the eleventh century. Furthermore, a daughter of a property-owning family was entitled to the family house

Murasaki Shikibu at work, illustration by Suzuki Harunobu, eighteenth century. (Burststein Collection/Corbis)

➤ SEI SHONAGON AND *THE PILLOW BOOK*

Sei Shonagon (fl. late tenth century) was the author of *The Pillow Book* (*Makura no soshi*), one of the great classics of Japanese literature. A descendent of a long line of noted scholars and poets, she was born around 965 and served as a lady-in-waiting at the court of Empress Sadako (976–1001). Sei Shonagon married at least once and apparently had several liaisons that produced at least one child, a daughter. She became famous for her quick wit and cynical but amusing commentary, and she won a reputation for her familiarity with the Chinese classics, considered an unusual accomplishment for a woman.

The Pillow Book is a masterful collection of eyewitness narratives, casual essays, impressions, reflections, lists of things that the author likes and dislikes, and imagined scenes. Writing in a highly cynical manner, Sei Shonagon vividly describes the affairs of men and women at court, but she also dwells on a wide range of topics including vivid descriptions of the four seasons.

In addition to fascinating descriptions of goings-on about the court and musings on life and nature,

The Pillow Book includes lists of items such as “Things That Cannot Be Compared” and “Things That One Is in a Hurry to See or Hear.” Few of Shonagon’s lovers please her, though, finding themselves included in her list of “Things That Irritate Me.” Apparently, they snored and stumbled around in the darkness the morning after while trying to find their clothes and fans and in general behaved like inept lovers. The author sought a world more structured to meet her likes and dislikes: Young people, babies, and high-ranking government officials should be chubby; if they are not, they look “nervous.” “A [Buddhist] priest should be handsome,” she asserts, “to make the worthiness of his sermon easily appreciable,” but an unattractive priest might cause his congregation to become sinful.

and a share of family income when an inheritance was divided. Some upper-class women became important leaders in society and were well educated and highly literate.

The status of women began to decline during the Nara period (710–794) and reached new lows in the Heian era (794–1185) and throughout the medieval period (1200–1600). There is much speculation as to why Japan shifted clearly to a more patriarchal pattern and women lost considerable status. Confucianism and Buddhism imported from China via Korea emphasized the central role of men and the subservient position of women in society. Wealthier or high-ranking families increasingly used marriages as a way of cementing ties between families and/or increasing the wealth of the family, with little thought to love as the foundation. Starting with the Taika Reform in the mid-seventh century, women were barred from becoming government officials, and a woman’s share of government-distributed land was set at two-thirds of that for a man. It was also stipulated that women could no longer hold

the office of emperor, a rule that holds true to this day.

Women in Japan, however, never reached the lowly status of women in traditional China and Korea. Upper-class women continued to be well educated and quite literate. Japan’s leading writers during the Heian period, most of whom were centered around Japan’s vast imperial court in Kyoto, included many women. While male courtiers struggled to master the more prestigious imported styles of Chinese poetry and prose, female writers were free to write in their native language. The great women writers of the Heian period include Ono no Komachi, Lady Ise, Sei Shonagon, Murasaki Shikibu (973–1014/1025), Izumi Shikibu, Akazome Emon, and the authors of highly poetic diaries such as *Kagero Nikki* (*The Gossamer Journal*), *Sarashina Nikki* (*Lady Sarashina’s Journal*), and *Sanuki no Suke no Nikki* (*The Emperor Horikawa Journal*).

The masterpiece of Heian literature is Murasaki Shikibu’s very long novel, *The Tale of Genji* (*Genji Monogatari*), composed in the early

eleventh century. Murasaki traces the life of a fictional handsome prince, Genji, through his marriage at court and his many subsequent romantic affairs. Whereas *The Tale of Genji* is noteworthy for its psychological insight on a fictional level, Michitsuna no Haha's *Kagero Nikki* (*Kagero Diary*) is a poignant autobiography describing a noblewoman's anguish and anger over her husband's many open affairs with other women at court.

The works of these women writers were widely read, often causing rivalry among the authors as well as caustic comments in their own journals. One famous statement found in the journal of Murasaki Shikibu concerns her contemporary Sei Shonagon. Murasaki had a rather low opinion of her, ignoring the older author's wit and focusing instead on her allegedly shallow learning and aggrandizing nature, as this excerpt from Murasaki's *Diary* illustrates:

"Sei Shonagon: the very picture of conceit and arrogance. When one looks carefully at the compositions in Chinese script which she pretentiously scatters about, their inadequacies are legion. Anyone who takes such pleasure in making herself different from others, will inevitably fall in their regard and her fortunes will go from bad to worse. Once addicted to a life of glamour, she will proceed to give displays of her fine feelings even on the dreariest and most ridiculous occasions, and in her efforts not to miss out on anything exciting, she will as a matter of course become notorious for her triviality. What good can come to such inanity in the end?"

The status of women declined even further in the twelfth century with the end of the Heian era and the onset of the Japanese Middle Ages, when central authority broke down and regional military figures vied for power. The new warrior-based culture had little place for women or feminine literature.

The Parallel Cults of Mary and Guanyin

From the standpoint of theology, the Virgin Mary of Christianity and the bodhisattva Guanyin of Chinese Buddhism represent the presence and activity of positive feminine energy operating within the framework of their respective patriarchal religious traditions. From the standpoint of psychoanalysis and mythology, the subconscious functions performed by Mary and Guanyin are considered by many scholars to be similar, even overlapping, and exercise upon the human psyche a creative universal feminine power that transcends religious difference.

In the late nineteenth and twentieth centuries as the disciplines of mythology, anthropology, comparative religion, and psychoanalysis began to converge, religious and mythological motifs of particular cultures were increasingly interpreted as archetypes of the human psyche and driving impulses within the evolution of consciousness. Thus, the notion that these historical devotional cults operate in parallel derives more from modern scholarship than from historical links, although some fourteenth-century iconographical connections are now widely accepted by art historians.

Jungian psychologist Erich Neumann describes the feminine archetype as possessing both a static, elementary character (i.e., its role as a vessel or container) and a transformative character (i.e., its activity of reproduction and development). Within these feminine characters are positive and negative aspects of each. For example, a positive container might describe a nurturing womb or a fertile valley; a negative container might describe a trap or an unhappy home. Positive transformation might take the form of fruition or child rearing; negative transformation might be identified in such mythical motifs as child devouring or destruction. As

developmental phenomena, the negative and positive qualities of the feminine character can be arranged along axes whose poles are defined by such terms as “Great Mother,” “Virgin,” “Muse,” “Witch,” etc.

From this perspective, Mary and Guanyin both vividly represent the universal properties of purity, maternal love, life, healing, and compassion, and throughout history they have emblemized the highest qualities of the positive feminine. Yet the importance of Mary and Guanyin within their respective religious traditions exceeds their capacity to embody mere psychological categories. To the devotees of their respective cults, these two “goddess” types are widely and passionately venerated, whether as sanctified exemplars of humanity, as in the case of Mary, or as authentic divinities in their own right, as in the case of Guanyin.

Guanyin (Japanese, Kannon) is Chinese Buddhism’s representation of Avalokitesvara (Sanskrit), the Bodhisattva of Compassion, or Divine Mercy. A divinity of ambiguous gender in his homeland of India but clearly more male than female, Avalokitesvara’s metamorphosis into a compassionate goddess followed the establishment of Mahayana Buddhism in China and Japan.

Like all bodhisattvas, or Buddhas-to-be, Guanyin vows to refrain from entering into Nirvana, the final release from earthly existence, until all sentient beings on earth attain enlightenment. Known in Buddhist theology as the bodhisattva who “hearkens to the weeping of the world” (a literal translation of the names Avalokitesvara and Guanyin), Guanyin exhibits boundless compassion for suffering people and helps guide souls to Amido (Japanese, Amida; Sanskrit, Amitabha), the celestial Buddha, who reigns as lord of the Western Paradise. Images of Guanyin abound in Chinese and Japanese art, and enshrined statues of the goddess continue to draw endless streams of pilgrims, especially in Japan.

The Bible states that Mary of Nazareth was chosen by God to give birth to the Christ Child, Jesus. Mary’s willingness to submit to the divine will is considered an act of perfect obedience. According to Christian tradition, Mary conceived Jesus through the action of the Holy Spirit and gave birth to the founder of Christianity sometime around 4 BCE. While legends of Mary’s sup-

posed association with the Essene monastic community can be found in a number of apocryphal sources, the traditional Christian teaching is that she gave Jesus a conventional Jewish upbringing and was among his very first followers. The first miracle recorded in the New Testament, the transformation of water into wine, was performed by Jesus on Mary’s request and is said to be evidence that prayers by the faithful directed to Jesus through Mary are especially efficacious. Mary appears to have been with Jesus at every stage of his career, up to and including the crucifixion in Jerusalem when, according to scripture, Jesus entrusted the care of his mother to the apostle John.

Mary is believed to have lived with John in Ephesus or Jerusalem for the remainder of her earthly life. According to teachings that became dogmatic in the Roman Catholic and Eastern Orthodox faiths, Mary never died but was rather assumed bodily into heaven, where she remains in the perpetual presence of her divine son. She is venerated by Eastern Christians and Roman Catholics as their heavenly queen and spiritual mother, a redemptive counterpart to their natural mother, Eve. As such, Mary prays for the souls of human beings, engages in battle with Satan, and, in keeping with a long tradition of Marian apparitions, which are popular in the Catholic Church’s traditions, occasionally makes direct contact with people on earth, offering admonition, consolation, and encouragement.

The cult of Mary has gone through a number of transformations over the centuries. In late antiquity and the early Middle Ages, veneration of Mary seems to have resonated closely with the worship of older pagan goddesses such as Isis, Astarte, Aphrodite, and Diana. In times of crisis, from the challenge of the Albigensian heresy of the twelfth and thirteenth centuries through the Protestant Reformation and into the twentieth century, the Catholic Church turned to Mary for help in delivering Christendom from wickedness and impiety. Praying the holy Rosary, a practice that emerged in the thirteenth century as a Latin Christian response to heresy and the Islamic resurgence in the Holy Land (but an aid to prayer that had origins in Hindu and Buddhist religious practices, with the rosary serving as one of Guanyin’s primary iconic symbols), continues into the

present day as a popular devotion among those who venerate the Blessed Virgin.

As is the case with Mary, Guanyin's influence and intercession are believed to be irresistible in the courts of Heaven, and also like Mary, she is seen by the faithful to possess such limitless grace, compassion, and power that she perpetually transforms and revitalizes the patriarchal structure she inhabits. In their capacity as primordial Great Mothers, Mary and Guanyin give life to the very gods that create them, and as personified sources of positive feminine energy, they mediate and transform the overweening influence of male power in a patriarchal world.

Gender and Politics in Byzantium

The gender most associated with politics in Byzantium is male, especially as for the most part men authored the sources, and their biases are recorded therein. However, the eleventh through fifteenth centuries saw a rise in elite female participation in the Byzantine world, including as business owners, patrons, authors, and power brokers.

The eleventh century had empresses who ruled in their own right, including Zoe and Theodora (who were returned to power in 1042 by a mob of both men and women), but there were also other women who exemplified female political influence in Byzantium in this period. This empowerment, to use a modern word, may have started with the education of women as attested to by no less a source than Michael Psellos, who recorded the lives and deeds of the tenth- and eleventh-century emperors and empresses but who was referring to his own daughter. Most famously, Anna Comnena authored the *Alexiad*, one of the main sources on her father's (Alex-

ius I Comnenus, r. 1081–1118) reign and was clearly educated not just in reading and writing but also in a wide variety of classical disciplines and authors. This education allowed her to play a more active role in advocating for her husband (Nicephoras Bryennios) against her brother John (later John II Comnenus, r. 1118–1143), and even after that she failed as an advocate against John and his son Manuel.

One of the most useful aspects of Anna's writings is that she preserved stories about other strong female political advocates, something that many male authors failed to do, including stories about her grandmother Anna Dalassena and her mother Irene Doukaina. Anna Dalassena was a role model for Anna Comnena and a particularly good example of a woman in politics. She was appointed as regent for and by her adult son Alexius I when he was off on military campaigns against Robert Guiscard. Irene, Anna Comnena's mother, fought off the dowager empress Maria's assault on her position, an attempt to gain the ear of Irene's husband, and Irene helped her daughter advocate for Bryennios against her own son and also followed her husband on his many military campaigns. In the twelfth century, Euphrosine, wife of Alexius III Angelos (r. 1195–1203), was the main power broker in the empire and the source of imperial favor. She also managed to survive charges of infidelity and subsequent banishment, returning later to her former position of influence in Constantinople, a clear illustration of one of the problems that women in political positions had in Byzantium. Though none of these women ruled alone, they were incredibly influential figures who strengthened Byzantine rule.

Women did not have to be empresses to have political power. Another Irene, the wife of Andronikos Comnenus (son of John II), was a patron of the arts and also opposed Manuel Comnenus (r. 1143–1180), for which she was politically persecuted. Manuel's daughter, Maria Porphyrogenita, led the aristocrat's plot of 1181 against her stepmother Maria of Antioch, who was acting as regent for Maria Porphyrogenita's brother Alexius (r. 1180–1183), two examples of powerful women. Maria Porphyrogenita turned Hagia Sophia into an armed camp, recruited foreign mercenaries, organized armed combatants fighting

► THE LAST OF THE MACEDONIANS

Zoe and Theodora, daughters of Emperor Constantine VIII (r. 1025–1028) and *porphyrogenitae* (daughters “born to the purple,” whose fathers were reigning emperors when they were born), were the last of the Macedonian line of Byzantine rulers. Zoe, the elder, was married to Romanus III Argyrus when her father died in 1028. Inasmuch as power had to pass through the Macedonian line but only to a male ruler, her husband became emperor by reason of his marriage. She remained empress for the next 22 years through three successive imperial husbands (Romanus III, Michael IV, Constantine IX Monomachus) and a period of co-rule with her sister in 1042, whom Zoe despised. During this time though she focused mainly on her own interests, such as perfume making. The passage of the imperial throne was often aligned with Zoe’s interests. Early in Zoe’s rule as empress, Theodora had been sent to a nunnery. However, during the misrule of Michael V (Zoe’s adopted son), the Byzantine Church and the people of Constantinople united behind both sisters and their bloodline to expel him and place the sisters on the throne where they ruled in their own right for less than a year. They remained co-empresses through Zoe’s third, and final, marriage to Constantine IX (r. 1042–1055). After Zoe and Constantine IX’s deaths, Theodora reigned alone from 1055 to 1056. Theodora’s death in 1056 ended the once great Macedonian dynasty. She named as her successor a man, Michael VI, who was favored by the aristocracy in Constantinople but was hated by the Church and the military, and he was overthrown within a year.

—Christian Raffensperger

on the streets of Constantinople, and eventually helped Andronicus Comnenus (r. 1183–1185), her cousin, to the throne. Both women were powerful figures in Byzantine politics and were treated as such by both friends and enemies.

Though unusual, it was also not unheard of for a woman to participate in or direct military operations, especially in the last centuries of the empire. Irene, wife of John VI Cantacuzenos (r. 1341–1354), was commander of multiple military units during the civil war of 1341–1347 and was also responsible for the defense of Constanti-

nople in 1348. Another active participant in the civil war was Empress Anne of Savoy. Anne had been the wife of Andronicus III and was regent for their son John V (r. 1341–1376, 1379–1391), against whom John VI was revolting (or at least against his government). Anne was deeply engaged in the war, including pawning her royal jewels in Venice, negotiating for 6,000 mercenaries from the Turks to be sent to fight against Cantacuzenos in 1346, and even attempting to reconcile the Latin and Orthodox churches as part of an attempt to preserve the empire.

Elite women had many political opportunities available to them, and some (like those illustrated here) took advantage of them. However, the vast majority of women in Byzantium were restricted from the political process. Women, in general, were sequestered away from men, were discriminated against in law, and had few opportunities for advancement or political power. It must be remembered that the women presented here are members of the noble class, and though not unique in their class, they were unique for their gender and their time.

Eve and Mary—Western Christian Attitudes toward Women

From 1000 to 1500 CE, Catholic theologians reiterated frequently a twofold idea drawn from scriptural interpretations of the early Church Fathers. At the turn of the fifth century, St. Jerome (d. 419) succinctly stated this idea with the formula “death through Eve, life through Mary,”

while St. Augustine (d. 430) exoterically phrased it as “through women, death; through women, life.” Six hundred years later, a group of reform-minded theologians revived this contradictory and paradoxical idea. Their works would have a profound impact on shaping the misogynic attitudes of the high clergy in the Latin West.

The increasing discussion of women as origins of evils symbolized by Eve was closely linked to the church reforms of the eleventh century, later named the Gregorian Reform after Pope Gregory VII (r. 1073–1085). The reformers, as part of their program to restore papal authority over the Church and to free ecclesiastical institutions and the clergy from secular interventions, campaigned vehemently to improve the morals of the clergy. This campaign quickly led to the reformers’ establishing canons (ecclesiastical rules) to regulate the daily lives of priests and also encouraging the laity to cherish celibacy as a virtue. In order to achieve these goals, reforming theologians, appealing to what they perceived to be the tradition of the early Church Fathers, revisited and repeated the dual arguments that women are subordinate to men because Eve had been created by God from Adam’s rib and that women should be held responsible for the fall of humanity because Eve, after being seduced by the serpent, had persuaded Adam to taste the forbidden fruit in the Garden of Eden. Not only were the theologians able to persuade their audience, both lay and ecclesiastical, that those arguments were grounded in the Bible and therefore true, but they also became more willing than their predecessors to derogate women as the weak and wicked sex, the deadliest trap for men, the root of all human evils, and the victims of their own voracious flame. Sometimes their rhetoric was only a small step away from condemning all women as prostitutes simply because the early Church Fathers established that Eve’s deception had caused the fall of humanity from God’s grace.

Affirmation of these teachings by the Church’s hierarchy was a very different matter from implanting these ideas in people’s minds and affecting people’s daily lives. The time period of Gregorian Reform (ca. 1049–1122) also witnessed the rapid growth and spread of Marian veneration, which led to the flourishing of cathedrals

Left: Eve, from *Adam and Eve*, by Albrecht Dürer (1504); Right: Virgin Mary with Christ from the Mosaic of the Donors, Hagia Sophia, Istanbul, Turkey, eleventh century. (Library of Congress/Jupiterimages)

dedicated to Notre Dame (Our Lady) throughout twelfth- and thirteenth-century Western Europe. This trend was due to a concatenation of multiple social and cultural changes of the most profound sort: the feudalization of land and property, the revival of urban trade and commerce, various movements of popular piety, the revival of Greek learning, new emphasis on pilgrimage, and the crusades. Most important of all, female voices began to be heard, including the voices of aristocratic ladies as they resonated in chivalric literature. These ladies demanded the powers, properties, and privileges that they deserved, and most of all they desired the love and dignity manifested in the Virgin Mary.

Clerical responses to this trend were perplexing. On the one hand, the reform-minded theologians, again appealing to the tradition of the early Church Fathers, affirmed Mary as the Virgin Mother of the God-man, Jesus. At the same time, they emphasized that (1) since the virginity

of Mary existed before, during, and after delivery, celibacy and virginity as a lifestyle ought to be preferred to marriage; and (2) since the Virgin Mary gave birth to Jesus without being tainted by Original Sin, she became the mediator of God's grace for human redemption from the curse of Eve. Moreover, highly placed Catholic clerics, while accepting and even embracing the growing popular devotion to the Virgin Mary, purposefully identified St. Mary Magdalene as a former prostitute and sexual aberrant who was brought to grace only through a total repudiation of her sexuality. This campaign to distort the character of Mary Magdalene was not accidental. There was a well-concerted effort by theologians to composite such a Mary based on at least three Marys mentioned in the Gospels and to persistently link Mary Magdalene, the supposed reformed prostitute, to Eve in order to pinpoint the intrinsic moral defects of women and to underscore the belief that such fallen women could only be saved through an asceticism that included total sexual abstinence. Thus, the two Marys, although given radically different spiritual biographies, were equally employed to emphasize the value of virginity and sexual abstinence. What is more, the Virgin Mary was upheld as the New Eve who participated in the redemption of fallen humanity through her willingness to bring into the world her son Jesus, and Mary Magdalene became a redeemed Eve by virtue of her devotion to that Son and her total repudiation of her former life of sensuality. Interestingly, neither Mary was ever viewed as a symbol of liberation for morally and socially suppressed women, at least so far as high clerical culture was concerned.

From the thirteenth century onward, scholastic theologians recast Catholic doctrines within the context of a new interest in Aristotelian logic and philosophy. Thomas Aquinas (ca. 1225–1274), the greatest of these theologians, devoted significant amounts of energy to synthesize a rational, universal truth regarding women's status. On the one hand, he compared Aristotle's argument that a female is a defective male (because of her lack of male genitalia) and thus has no vital force with the biblical story that Eve was created from Adam's rib. This comparison confirmed his belief that women were, indeed, created sep-

arately after men and from men by God's grand design and should be therefore subordinated to the rule of men. On the other hand, he also expanded the role of the Blessed Virgin Mary from the mediator for human redemption to the intercessor between Christ and humanity. In one of the prayers he composed, he taught that as the Mother of God she was therefore the Mother of all humans; she was the Mother of the kingdom of Heaven and therefore the refuge of all human needs. It was her mercy that the believers embraced more fondly, thought of more often, and invoked more frequently, and it was through her grace that humans found God. Thomas's scholastic Mariology not only consolidated the traditional Catholic Marian doctrines—the Mother of God and the Perpetual Virgin—but also laid the foundations of the new doctrines of the Immaculate Conception (her being conceived in her mother's womb without the stain of Adam and Eve's Original Sin) and the Assumption (her having an incorruptible body by virtue of her total sinlessness and therefore her assumption into Heaven in body as well as in soul). The Roman Church was tolerant of the spread of these two pious novelties because both were believed to have also been rooted in the traditions of the early Church Fathers. Now, a more humanistic image of Mary changed somewhat social perceptions of women, who could be loving wives and devoted mothers, adored mistresses in a courtly romance, or even virtuous women who would help men move toward that which was good, such as Dante's Beatrice. Regardless of the Virgin Mary's status as intercessor for all humankind before the throne of her Son and her new role in elevating the status of women so far as some social norms were concerned, the Church showed no intention at all to change its misogynic attitude and teachings.

The new waves of popular piety that centered on the Virgin Mary coincided with the more humanistic Mariology in late medieval Europe. Both, in turn, flourished in Renaissance art and literature in which Mary became a central figure of humanity as well as of divinity. However, controversy surrounding the character and the nature of the Virgin Mary continued in the Latin Church. Emphasis on the humility and passivity of Mary continued to dominate Catholic theology,

despite the growing popular belief that she was the model of motherhood and the mediator of all graces. Attempts to praise her in order to empower women in the church hierarchy and to promote women's rights in the real world often ended miserably, with women being condemned as heretics and even burned at the stake by Catholic authorities. Soon, Protestant hostility toward Mariolatry (the Protestant term for what they perceived to be undue worship of Mary) emerged as a basis for iconoclastic campaigns against the Catholic establishment and its Marian art.

While the Blessed Mary did not bring about the liberation of women at the end of the Middle Ages, the weak, sinful, and wicked Eve would stay in the elite and the popular culture of the West for centuries to come.

Women in China and the Latin West

There were many similarities between the lives of Chinese and European women during the period between 1000 and 1500, but there were also interesting differences in household living arrangements, laws pertaining to marriage and divorce, and perceptions regarding the inherent nature of females. Both societies were steadfastly patriarchal, but, in both cultures, male domination was more of a societal norm with

origins in the distant past rather than an overt manifestation of contemporary misogynistic tendencies. Both societies were intent on regulating female behavior.

In the Latin West, early medieval Latin Christian theologians constantly reiterated the idea that virginity and chastity were preferred moral values, as opposed to sexual desires and activities. At the same time, these church leaders conceded that marriage was legitimate because it was the necessary instrument of human continuity, it was a means of avoiding sexual promiscuity, and it was blessed by Jesus at Cana. Yet, virginity was still considered and taught to be a "higher, more spiritual calling."

In order to reconcile the heavenly ideal with mundane reality, Latin theologians developed a system of extremely complicated theories on womanhood and sexuality. While acknowledging that women were equal to men in Christ's redemption of them from Original Sin and in their potential for salvation, theologians shared a firm conviction that women inherited a weak and wicked nature from Eve, and were largely incapable of resisting diabolical temptation. Moreover, their ability to tempt men sexually caused them to be considered by some Christian theologians to be the "Devil's Gateway" to sin and, therefore, morally inferior to men.

Even nuns were treated and regarded differently from monks, their male counterparts. The Church reformed and consolidated female monasticism by affirming nuns' spiritual dedication to God and encouraging their ascetical life styles as avenues to moral perfection, but the Church also placed nuns under the supervision of men, either monks or bishops. Although a few nuns were canonized as saints by the papacy, leading theologians never failed to point out that, while their spiritual devotion was indeed commendable and admirable, their sanctity, however, came from the gift of prophecy and all it entailed, or from the grace of God. The literature of nuns themselves seldom disputed the inferior status of women in this world, and often accepted the teaching of women's secondary role in God's creation.

In the early thirteenth century, the Church finally sanctioned marriage as a grace-giving sacrament on the basis of a theological metaphor

► THOMAS AQUINAS ON WHY A WOMAN'S SECOND MARRIAGE IS NOT A SACRAMENT

“Although a second marriage taken in itself is a perfect sacrament, yet taken in relation to a first marriage it has something of a defect in the sacrament, since it does not have full signification, since it is not of one woman to one man, as with the marriage of Christ and the Church; and by reason of this defect the [Church’s] blessing is withdrawn from the second marriages. But this should be understood of the case where the second marriage is the second for both the man and the woman, or for the woman only. For if a virgin contracts marriage with a man who has had another wife, the marriage is blessed none the less: for the signification is in some way preserved even in relation to the first marriage, since Christ, even if he had a single Church as a bride, nevertheless has many persons within one Church as brides; but the soul cannot be the bride of any other but Christ, since with the demon it commits fornication, and there is no spiritual marriage there; and because of this, when a woman marries for the second time, the marriage is not blessed because of a defect of the sacrament.”

that allegorized the relationship between the Church and Christ as a holy union. However, some theologians used this metaphor to emphasize that marriage was the reintegration of women with men after Eve’s betrayal and fall, and, in addition to biological necessity, it was a moral path—by which the inferior female would go back to the guiding principle, the male. Moreover, Western Europe’s culture of the time revealed an ambivalent attitude toward women in the dualist symbolism of Eve versus Mary: the sinning temptress versus the sinless virgin mother of Christ.

To thirteenth-century Neo-Confucian scholars in China, women were not the Devil’s Gateway;

rather, they were malleable and could be brought to virtue, if men would dutifully guard the family’s gateway to keep the devils out. Influenced by the Turkic steppe peoples, the ideal male of the Tang dynasty (618–907) had been a literate warrior with a strong interest in athletic pursuits, hunting, and warfare. Rejecting the “barbarian taint” of the previous dynasty, the ideal Song male (960–1279) was a refined, sensitive scholar who spent his time in intellectual and artistic pursuits. Redefining masculinity necessitated a reevaluation of proper characteristics and behavior for women. Song-period Chinese emphasized a more restrictive approach based on the *san-cong* (the three obediences) in which daughters obey fathers, wives obey husbands, widows obey sons.

If the ideal Chinese male became more intellectual and less active during the Song era and in the subsequent Yuan period of Mongol rule (1279–1368), the ideal woman became an exquisite flower with “lotus feet,” faithful to her husband even after his death. Historians have not precisely identified the origins of footbinding, but it is clear that the practice became spread far beyond court circles during the Song era, perhaps as a means of emphasizing the fragile delicacy of Chinese women. Mongol women, who had considerable freedom even at the Yuan court, were prohibited from binding their feet, but their freedom does not seem to have been transferred to their Chinese counterparts. During the Yuan and Ming (1368–1644) periods Chinese women were also burdened with other restraints, particularly regarding diminished control of their dowries and their increasing inability to retain them after being widowed or divorced, thus substantially limiting the resources available to them.

In theory, Daoism and Buddhism challenged Confucian social structures. Confucianism’s primary goal is to provide a blueprint for a well-ordered hierarchy. A wife’s relationship with her husband would ideally be a replication of a subject’s relationship with a monarch; theoretically, a husband was required to act in a wife’s best interest, just as a ruler was responsible for the well-being of his subjects. As discussed below, reality was much more complex. Daoism, a more mystical approach, tended to associate female power with creativity. One passage of the *Dao*

Dejing: The Classic Book of Integrity and the Way, translated by Victor H. Mair, advises, “Having realized the mother you thereby know her children. Knowing her children, go back to abide with the mother. To the end of our life, you will not be imperiled.” Buddhism, a missionary religion, was introduced to China from Persia (present-day Iran) and points east some time around the first century CE, and was widely disseminated by the Tang period (618–907). Buddhism had broad appeal, but was particularly attractive to women, with its basic assumption that women were equal to men in their ability to seek spiritual fulfillment.

While classical Chinese philosophy generally promoted the notion that women should be in a supportive role at the bottom of the hierarchy, there was little or no implication that females were inherently any more or less evil than men. Nevertheless, there were always cautionary tales about hen-pecked husbands and shrewish wives. Most were comedies, but some were presented as tragedies, wherein the shrew’s husband, mother-in-law, father-in law, or all three died of shock and shame over her vile behavior.

Beginning in the Song era, a succession of Chinese scholars known as Neo-Confucians redefined the cosmic balance of the female principle, or *Yin*, and the male principle, or *Yang*, a balance that they viewed as the origin of and purpose behind both the natural universe and all Chinese social and political structures. The foundation of this cosmic balance was the gender harmony that existed in all families, in which men ought to fulfill “outer” duties and women “inner” duties. In a family, *Yang* and *Yin*, corresponding to the husband and the wife respectively, were metaphysically interdependent, and the “outer” duties of the man and the “inner” duties of the woman were complementary. Instead of justifying a husband’s right to his wife and his power over her, the cosmic Moral Principle of Harmony known as *Li* demanded that the husband was expected to provide for the family and protect the family members, including his wife. Meanwhile, instead of maligning a wife’s inherent moral character because she was a woman, *Li* taught that the wife was expected to *perfect* her manners, which were moral qualities, and thereby better the household in order to please

all family members, especially her husband. This Neo-Confucian deontology, a code of duty-centered ethics for both man and woman, idealized gender relationships and soon became the core value of the family. It was this idealized family that epitomized all socially and politically constructed networks in China.

Arranged marriages—often entered into for reasons of prestige or to forge ties between families—were the norm for upper classes in both societies, although it appears that it was far less ubiquitous in the lower rungs of European society. Dowries were important in both societies as well, but the degree to which a woman controlled her dowry varied from place to place and time to time in both. Although they were somewhat more likely to impoverish a bride’s family in China, particularly during the Song dynasty, they could be burdensome in Europe as well. Both societies stressed the importance of order in family hierarchies. A Chinese male, if his family had sufficient wealth, might have many concubines, but he could have only one wife at a time. A wife could sometimes limit or shape her husband’s behavior, but his mother would have a greater influence. The adult males of Chinese families were rarely intimately involved in the day-to-day issues of household management or child rearing; women bonded closely with their sons. A husband’s authority was subject to his filial duty to his parents. In practice, a husband’s mother ruled the household. A young wife might be oppressed; if she survived, she would also know that she would be likely to rule her own sons’ wives some day.

In China, lineages comprised of households with concubines and maids (generally sexually available to their master) were likely to grow faster due to a high birth rate. This growth rate was seen as a distinct advantage, but there was one complication: up to 20 percent of Chinese males were not able to secure wives or concubines for themselves. Women could generally better their status by marriage or by becoming affiliated as a concubine or maid and move up in the hierarchy, but the high percentage of unattached males constituted a problem, particularly during times of unrest or economic downturn. During periods of famine or other hardships, a husband’s parents exercised birth control by

keeping young married couples apart. Unwanted pregnancies, proof that couples disobeyed parental guidance, were a source of embarrassment, and heartily condemned by older family members. There were instances of young wives committing suicide rather than facing family condemnation.

Women had few options available to them during times of family discord or disruption. Men could initiate divorces for misbehavior (such as talking too much and being disrespectful), but women could not. By the period of the Ming dynasty, a husband had full control over his wife, concubines, and maids, subject only to his filial duty to his parents. From the Song dynasty onward, widow remarriage was frowned upon, but even though the aspect of romantic and sexual loyalty to one's husband is emphasized in Chinese literature, it seems more likely that the prohibition grew from a concern about property rights. If a widow left her husband's family for that of another man, she might have a claim to the family property—and her sons definitely would. Widow remarriage could well diminish the holdings of the family, a serious issue in a society organized around male lineages. Unlike European women, Chinese women did not have recourse into a celibate religious life, except those very few who opted to become Buddhist nuns—a choice that was less available to women, with the state's closing down and secularizing many Buddhist monasteries and nunneries in the mid-ninth century. Even a Buddhist revival under the Yuan and Ming emperors did not substantially raise the number of Buddhist monastic retreats.

The various cultures of Europe also underwent dramatic changes during the period 1000 to 1500. By the eleventh century, the Church had assumed a leadership position, albeit within the context of a continuing struggle with secular emperors, kings, and princes. Regardless of this power struggle for a position of primary authority over the lives of Western Europeans, by and large the Christian concept of women's role in the world (secular as well as sacred) had become ubiquitous. After the eleventh century, perceptions about the nature of women came primarily from the pens of men, many of whom struggled with their own sexuality. Eve was the temptress, whose transgression brought pain,

sin, and death into the world. The sexuality associated with Eve seems to have been especially threatening to monks, who had taken vows of perpetual chastity, and to a priesthood for which the state of celibacy was becoming increasingly the mandated norm. It should be noted that not all men found women to be as menacing as did pious churchmen, but the association of women with sin did at times endanger non-conforming women.

Nevertheless, the Church was patronized by wealthy women. These patronesses seem to have been motivated by a desire to do good works, but one cannot avoid theorizing that some of these women had internalized the Mary/Eve dichotomy and were striving for virtue. By the fourteenth century, there was unease about aggressive women, called “viragos” in English (literally, “one who acts like a man”). There was some concern that the heat and intensity of these assertive women might cause them actually to grow penises, thereby disrupting the entire order of the world.

Despite their different theoretical approaches, both Neo-Confucian scholars in China and Christian theologians in the Latin West would agree that women should be kept out of the public sphere and perform domestic duties: giving birth and taking care of children, preserving order in homes, and offering love and comfort to their husbands. Both would even agree tentatively that virtuous women at home could help men achieve moral good in public. However, in the Latin West, although women were constantly reminded of their moral defects, peasant or common women might enjoy the limited right to choose their marriage partners; a wife could expect to live with one husband at a time protected by the Church's law of monogamy; and a widow could exercise some degree of discretionary authority over her property, as permitted by law. Most of all, the West's feudal law of primogeniture did not totally exclude women from holding property, and women of substance could, therefore, enjoy limited autonomy and exercise some authority over their property.

In China, by contrast, a woman's private freedom was much more constrained by the social norms prescribed by Neo-Confucian teachings, namely the three obediences. A girl was expected

to obey her father's choice of her future husband; a wife was expected to obey her husband totally and to be tolerant of his concubines and fair to their children, especially when she could not reproduce a male heir; and a widow was expected to obey her eldest son. Moreover, a woman should demonstrate her *si-de* (four virtues) in front of men: her dignified grace, delightful beauty, decorous vocabulary, and domestic artifices. Within the bondage of those invisible norms, an aged wife might exercise her authority over the domestic affairs of her family, often after her grown-up sons married and fathered their own children. However, she ought to continue dutifully obeying the decisions of her husband, respecting her parents-in-law's disciplining her sons and daughters-in-law properly, and managing the complicated relationships among family members skillfully and fairly.

Sometimes, a woman might become the head of a family, when she was widowed and acknowledged as the regent of the heir, her son, particularly if she had earned respect from the male members of the family by embracing and perfecting her feminine qualities. At the same time, a woman, especially a concubine, might endure many years of manipulation and humiliation in order to demonstrate her moral perfection and earn herself respect from the family members. Her husband could easily desert her, if she was unable to fulfill her primary duty of reproducing children, especially a male child. The most miserable treatment that a woman had to endure in the duty-centered family network often befell a young widow, who happened to be a concubine without a male child of her own. She was expected to remain chaste in honor of her dead master and to commit suicide if she was accused of a promiscuous deed or was sexually violated by a man. No law required her to do so, but social norms were often powerful enough to induce such tragedies.

In the public sphere, women in neither Europe nor China were allowed to hold government offices, to serve in the military, or to be ordained priests, although European women could hold positions in some trade and even merchant guilds in parts of the West. Both the ecclesiastical and secular laws of the Latin West intentionally excluded women from performing most

SEVEN REASONS TO DESERT A WIFE

Neo-Confucian scholars listed seven reasons, alleged to be the words of Confucius, for a husband to desert his wife:

"Disobedience to her husband's parents, failing to produce children, being licentious, being jealous, having an incurable disease, being too talkative, and stealing."

"Hsiao-hsueh chi-chieh," edited by Chang Po-hsing (1651–1725), in *Kuo-hsueh chi-pen ts'ung-shu*, edited and reprinted (Taipei: Commercial Press, 1968), p. 35. Translation by Wenxi Liu.

public functions, and similarly Neo-Confucian scholars viewed women's entry into the sphere outside their families as breaking the harmony of the cosmic order, which would inevitably lead to disasters.

There actually were a few brilliant queens in Europe during the period 1000–1500. These women fought industriously either for their own hereditary rights or on behalf of their children's legitimate claims to power, and their struggles to obtain what belonged to them (thrones, fiefs, and hereditary offices) often earned them respect and support from their subjects. In China, on the contrary, there were neither empresses nor prominent female politicians during the same period. Moreover, Neo-Confucian scholars always depicted Empress Wu Zetain (625–705) of the Tang dynasty, the only Chinese woman ever to hold imperial power in her own right, as an evil ruler daring to surround herself with Buddhist monks and other evil advisers who forged a Buddhist sutra to legitimize her usurpation of her husband's throne. She is also accused of committing murders and various other abuses of power, as well as encouraging evil men to satisfy her scandalous sexual appetite. This misrepresentation of Empress Wu successfully persuaded emperors of the Song and Ming dynasties to implement laws prohibiting women's participation in politics.

During this time period, Neo-Confucian scholars also harshly condemned a few imperial concubines who dared to involve themselves in court politics. In their minds, these women's political ambitions and promiscuous life styles threatened to not only debase court order but also to destroy the empire. Therefore, the resolute enforcement of *Li* throughout the centuries actually confined Chinese women increasingly within the "inner" circle of family and undermined their talents in public politics. Women did not have another opportunity to exercise real political power until the Qing dynasty (1644–1911), when ethnic Manchurians dominated China.

Despite institutional suppression and intellectual misogyny, many women in both China and the Latin West refused to marginalize themselves. Within the compressed private sphere, some struggled to educate themselves, write about their lives, and voice their concerns. Some of their literary works not only influenced women readers of their era but also left marks on future generations. The works of Christine de Pisan (ca. 1364–before 1430) in the Latin West and the poems of Lady Li Qingzhao (1084–after 1155) in China represented the highest literary achievements of their respective ages. With the growth of an urban economy and the expansion of trade and commerce, many townswomen became more visible in operating businesses independently in spite of legal restrictions and social biases against them. Literature gradually flourished, exploring the female awareness of their bodies, love, and sexuality, and indicating a desire to enter and compete in the male-dominated professions.

Some of the bravest female individuals were victimized in the West's witch-hunts of the late Middle Ages and beyond, simply because they dared to break the rules set by the Catholic Church. During the same time period, many women in China committed suicide in order to conform to the social norm of widow's chastity, after the first Emperor of Ming, Zhu Yuanzhang (r. 1368–1398), unprecedentedly sanctioned *chi* (integrity) as a virtue for the people, especially women. Except for a few such as Joan of Arc (ca. 1412–31) in the Latin West, most females, activists and victims alike, died unnoticed; they are,

however, being rediscovered, remembered, re-evaluated, and respected today.

Gender Relations on the Eurasian Steppe

The task of taking care of the animals, the very basis for life and livelihood on the steppe, was shared by both sexes. Men handled the animals unless they were hunting or away from the family for war or other reasons. Men also constructed the yurts (or gers) and wagons, although this often became a task for the entire family. In addition, they churned the *kumiss* and manufactured the saddles and other riding equipment as well as their own weapons.

Women did most of the household duties, such as cooking, making butter and other dairy products, dressing animal skins, and making felt. During migration periods, women also drove the carts and wagons. When the men hunted or were at war, the women would take care of the animals. It was not unusual for either sex to do the traditional work of the other.

All of the nomads had some proficiency as archers with the compound recurved bow of

the steppe, and both sexes were known for their equestrian skills. Children learned to ride at an early age, often before they walked.

Children assisted in the care of the animals but also had the duty of procuring fuel for the fire. As wood was scarce on the steppe and needed for the construction of yurts, bows, wagons, and other items, it was not used as fuel. Instead, children gathered dried animal dung, which if properly dried burned with little odor.

Due to the often precarious nature of life, which depended on men and women to frequently perform the same duties to ensure the family survival, pastoral nomads tended to have a strong egalitarian streak in their institutions. There was social and political differentiation but much less so than in the patriarchal agrarian societies that bordered the steppe. Egalitarianism was most apparent in gender relations, responsibilities, and social status. Even in the upper levels of society, women could play an overt role in politics, such as the regency of Töregene, a wife of Ögödei (r. 1230–1240), the second Mongol khan, who ruled the empire as regent from 1240 to 1246. Indeed, women frequently served as regents at regional levels for the domains of the Mongol princes. Mothers and wives also served as advisors at all levels of society. On several occasions Chinggis Khan (1162–1227) turned to the advice of his mother Hoelun as well as his wife Börte. Before setting forth against the Khwarazmian empire in 1219, he heeded to the suggestion of another wife, Yesui, and selected a successor. Women were still subordinate to men, but their nomadic lifestyle allowed for a wide latitude of flexibility.

➤ MARRIAGE AMONG THE EURASIAN NOMADS

Marriages were exogamous (outside of one's immediate kin) and often arranged while the intended husband and wife were young. It is not certain how extensive polygamy was among the nomads, but it existed among the nobility. Furthermore, the nomads also practiced Levirate marriages in which after the husband's death, the wife, if she agreed, could marry her brother-in-law. Furthermore, a son could also marry the wives of his deceased father, excluding his own mother, thus ensuring their economic security.

Western Concepts of Masculinity

Masculinity in the European Middle Ages was not a private matter of personal identity but rather a public performance of actions that had to conform to explicit cultural expectations. Aristocratic males, and to a lesser extent clerics and commoners, faced significant pressure to earn a reputation as real men in the eyes of their peers. Meanwhile, the Catholic Church sought to reorient traditional secular masculinity to fit with its own value system. Chief among the male impulses that the Church set its sights upon was the familiar tandem of sex and violence.

Men in the secular world were obliged to demonstrate their masculinity constantly lest they be stigmatized as effeminate. One of the primary ways to prove one's manhood was to engage in regular sexual intercourse. Men needed to keep their women sexually satisfied, for the medical philosophy of the day held that sex kept women in good health (and, since women were considered lustful, sex at home was thought to deter a woman's inclination toward adultery), and, of course, it led to conception, which the Church preached was the only legitimate purpose for this inherently sinful activity. Fathering many children, especially sons, was a typical sign of virility. Moreover, fashionable articles of clothing such as pointed shoes were meant to call to mind the male anatomy; indeed, one term for a manly yet stylish young fellow was *poulain*, from the Latin *polana* (pointed shoe). Such

► THE FUSION OF SECULAR AND SACRED

St. Bernard, in his treatise *In Praise of the New Knighthood* (ca. 1130), heartily advocated for knights to abandon their secular, materialistic ways (which he ridiculed as weak and effeminate) and instead to adopt a lifestyle that emulated the monk in piety and asceticism. Unlike monks, however, the new knights, specifically the military order of the Knights of the Temple, shed blood in the name of Christ. Killing infidels, Bernard assured them, was a holy undertaking because it was *malicide* (killing evil) rather than homicide. Never before had the spiritual masculinity of the church and the secular masculinity of the warrior class been so closely intertwined. Bernard argued that death in holy warfare was the best conclusion to a secular, or nonclerical, man's life:

"How blessedly martyrs die in battle! Rejoice, brave athlete, if you live and conquer in the Lord; but glory and exult still more if you die and join your Lord. Life is indeed fruitful and victory glorious, but more important than either is a holy death. If they are blessed who die in the Lord, how much more so are those who die for the Lord!"

youths chafed at the antisexual culture fostered by religious authorities.

Throughout this era the Church steadily attempted to restrict the sexual lives of clergy and laity alike. For much of the first millennium of its existence, the Church had tacitly tolerated marriage and concubinage among men of the cloth, but by the twelfth century clerical celibacy was becoming a rule and not just an ideal. Laymen, meanwhile, faced an increasingly complex system of ecclesiastical law, no small amount of which was dedicated to sexuality. Gratian's *Decretum* (ca. 1140), a compilation and synthesis of canon law, provided the Church with ample grounds for prosecuting men for their nonmari-

tal sexual encounters. There was little method for enforcement, though, so punishment could be evaded by the clever.

By the early fourteenth century the legal systems of secular governments had reached the sophistication of church law, and between the outbreak of the Black Death in 1347–1348 and the beginning of the sixteenth century, secular authorities rivaled their ecclesiastical counterparts in attempts to curtail sex. Like the Church, governments took a dim view toward nonmarital sex and prosecuted a wide range of activities, including masturbation, fornication, adultery, and homosexuality. If the law was strict for men, it was far worse for women. Men by far had freer sex lives, benefiting from centuries-old beliefs in the natural superiority of masculinity on both the physical and spiritual levels. Compared to men, women were seen as more sexually voracious, more likely to commit adultery, and more likely to be the cause of problems in marital relationships.

Males of the aristocracy, in turn, found a new model of manhood. Ideal masculinity for the warrior class had long been a matter of physical prowess. The Church had struggled in vain against the knightly proclivity toward violence, passing edicts such as the Peace of God, which tried to forbid aggression against the clergy and poor, and the Truce of God, which proscribed violence on certain days of the week. With the advent of the First Crusade in 1095–1096, however, the Church readily sanctioned masculine violence so long as it was channeled against more "appropriate" targets, such as the Muslims who ruled over Jerusalem and who were identified as the enemies of Christ. A major motivation for men who took part in the crusades was (as they saw it) to avenge Christ's death. Church authorities such as St. Bernard of Clairvaux (ca. 1090–1153) promised that the man who died a holy death in battle was a martyr and would earn a sure ticket to heaven.

Now the male roles of man of God and man of war could be fully reconciled in the person of the holy warrior. Earlier these two models of masculinity had been mutually exclusive, as seen in the evolving conception of the English king and martyr, St. Edmund. The historical Edmund was a king of East Anglia who died in battle against Viking invaders in 870. Chronicle ac-

counts give no indication that he was a particularly holy man, but after his death writers began to depict him as an ideal Christian who eschewed violence and willingly died as a martyr for Christ. In the two centuries following the First Crusade, however, Edmund was portrayed as a martial figure, though no less holy for his newfound bellicosity. He thus evolved from a character who emulated a peaceful Christ to an archetypal crusader who won God's love by dying in battle against His enemies.

Courtly Love, Romance, and Gender Stereotypes in Europe

In the twelfth and thirteenth centuries, French troubadours imagined a unique kind of male-female relationship, which they referred to as *fine amour* (refined love), for entertaining a targeted audience: aristocratic ladies. Since the late nineteenth century, this model of emotional and physical relationship has attracted both historians and literary critics as scholars search for the medieval traces of female gender consciousness and the origins of European misogyny. The *fine amour* is thus now commonly termed "courtly love."

Eleanor of Aquitaine (ca. 1122–1204), queen first of France and then of England, was the most powerful stateswoman in twelfth-century Europe, noted for her vigorous defense of her hereditary right to title, property, and privileges; for her role in the Second Crusade (1147–1149); and for her intrigue in the Franco-English conflict at the turn of the thirteenth century. Meanwhile, she was also the wealthiest and most

Manuscript illumination of troubadours performing before a royal couple, from Alphonse Le Sage's *Las Cantigas*, late thirteenth century. Troubadours were professional composers of music and poetry, and were among the chief entertainers in the royal courts of Europe. (Gianni Dagli Orti/Corbis)

colorful individual of her time, with a sophisticated taste in the arts, especially poetry, music, and fashion. It has long been alleged that in her court at Poitiers, she and her daughter Marie, countess of Champagne, generously received and entertained guests, mostly aristocratic ladies and their companions. Although whether and how often courtly love-styled liaisons between noblewomen and chivalric knights actually occurred inside the court remains murky, it is quite certain that a new literary genre—romance, with courtly love as the central theme—emerged from and circulated in that court. This new genre accommodated female courtiers and satisfied their psychological needs.

During Europe's High Middle Ages (ca. 1000–1350), a romance (*roman* or *romant*) meant a piece of popular courtly literature in verse and in the vernacular Old French, or *romanz*, language instead of Latin. Romance stories about

FROM ANDREAS CAPELLANUS, *DE AMORE*

“Know, then, that the chief rules in love are these twelve that follow:

- I. Thou shalt avoid avarice like the deadly pestilence and shalt embrace its opposite.
- II. Thou shalt keep thyself chaste for the sake of her whom thou lovest.
- III. Thou shalt not knowingly strive to break up a correct love affair that someone else is engaged in.
- IV. Thou shalt not choose for thy love anyone whom a natural sense of shame forbids thee to marry.
- V. Be mindful completely to avoid falsehood.
- VI. Thou shalt not have many who know of thy love affair.
- VII. Being obedient in all things to the commands of ladies, thou shalt ever strive to ally thyself to service of Love.
- VIII. In giving and receiving love’s solaces let modesty be ever present.

IX. Thou shalt speak no evil.

X. Thou shalt not be a revealer of love affairs.

XI. Thou shalt be in all things polite and courteous.

XII. In practicing the solaces of love thou shalt not exceed the desires of thy lover.”

“Not only is every woman by nature a miser, but she is also envious and a slanderer of other women, greedy, a slave of her belly, inconstant, fickle in her speech, disobedient and impatient of restraint, spotted with the sin of pride and desirous of vainglory, a liar, a drunkard, a babbler, no keeper of secrets, too much given to wantonness, prone to every evil, and never loving any man in her heart.”

Andreas Capellanus, *The Art of Courtly Love*, ed. and trans. John J. Parry (New York: Columbia University Press, 1941), 81–82 and 201.

Troy, Alexander the Great, Emperor Charlemagne, Roland, and King Arthur and his knights recast Germanic and Celtic epics, legends, and folktales, and the adventures of brave knights with their ladies, idealistic noblewomen who were often married to someone else, occupied center stage. On one level, the courtly love relationship was an imitation of the feudal relationship between a lord and his vassal, or warrior retainer. In many romance stories, the knight served his noble lady by following the norms of courtesy, obedience, loyalty, readiness to serve, and willingness to sacrifice his life in the same way that an idealized feudal vassal served his liege lord. This literary model of love invited contemporary criticism because it defied the ecclesiastical pronouncements on feminine inferiority and the sacredness of marriage. It also made secular noblemen feel uncomfortable because their marriages were usually connected to a convenient concern for inheritance.

However, the lyrics and poems of the courtly love model continued to grow in number and popularity, and courtly love turned from a cen-

tral element of romance stories into a code of love. Segregated noble ladies in various courts might dream of playing central and commanding roles in a real world. They might even fantasize breaking sexual taboos and challenging conventional virtues of womanhood. For most of them, however, a sexual or at least emotional relationship out of wedlock was of far lesser concern than fulfillment of the ideals of true love and nobility. Therefore, the code of courtly love mixed social reality with literary exoticism, religious doctrines, and philosophical speculations and was constructed with a set of inherent dichotomies that complemented one another: knightly bravery vis-à-vis courtly gentility, virginity vis-à-vis sexual escapade, passion vis-à-vis restraint, the art of love vis-à-vis accursed love. From the thirteenth century onward, norms of noble behavior and romantic love derived and refined from this mixed code gradually filtered down from the nobility to people of the lower social strata, which in turn gave the European ideals of nobility, genteel behavior, and romantic love a distinguishably paradoxical character.

Around 1200, a priest known as Andreas Capellanus (Andrew the Chaplain), who served Countess Maria of Champagne, produced (in Latin) the book *De Amore* (*Concerning Love*), also known as *De Arte honeste amandi* (*The Art of Courtly Love*), which he loosely based on the *De Amore* of the Roman poet Ovid (43 BCE–17 CE). Ever since its circulation, readers and commentators have been divided by the contradictions and ironies embodied in the chaplain's narratives and commentaries. Was it a primer aimed at teaching young knights the rules of courtly love to help them move up in the aristocratic hierarchy, or was it a scathing critique, denouncing extramarital and promiscuous sexual adventures while advocating a principle of true womanhood acceptable to the Church? Regardless of its author's intention, the last part of the book included extremely derogatory and vicious statements against women. Those misogynic remarks, even though they might have been sarcastically made as some scholars suggest, reflected a major and enduring aspect of an already centuries-old Western culture of gender and sexuality.

Alongside these sentiments, however, the West inherited other notions from the literary genre of courtly love, not only the idea that true love, as opposed to a marriage of convenience, is possible and even ennobling but also that the lover places his beloved on a pedestal, ironically thereby objectifying her. It has surely been an ambiguous heritage.

Transvestism in Western Culture—Saints and Sinners

Transvestism, or cross-dressing, is well attested in medieval European literature and culture, and provides a clear illustration of the premodern Western gender hierarchy that exalted males and masculine characteristics. Women who cross-dressed gained in status because they were seen to be making themselves more masculine, whereas men who did so were condemned unless their transvestism was overtly intended as harmless spectacle.

Cross-dressing was not disparaged in classical Greek and Roman times, when it was associated with the worship of deities such as Dionysus and Aphrodite. There are also myths of cross-dressing heroes including one about Achilles, who was disguised as a girl by his mother so that he would not be taken away to the Trojan War, an episode recounted in the *Achilleid*, the unfinished Virgilian epic of the Roman poet Statius (ca. 45–ca. 96 CE).

The Judeo-Christian tradition, however, was more hostile to transvestism. The practice was explicitly prohibited by the Hebrew scriptures (Deuteronomy 22:5), probably to distinguish Judaism from other faiths that did incorporate cross-gender rituals. Christianity forbade transvestism (though with no means of enforcement) at the Council of Gangra (before 341), claiming that women who tried to live as monks were doing so only in pretense of holiness.

It is difficult to say how many women did, in fact, attempt to disguise themselves as monks, but a vast tradition of such stories circulated throughout Europe in the early Middle Ages. The women, such as St. Eugenia, in these tales are depicted favorably and are admired for their cross-dressing. In the secular literature, the thirteenth-century French poem *Le Roman de Silence*, by Heldris de Cornuälle, involves a heroine named Silence who is raised as a boy in order to circumvent a law prohibiting women from inheriting. In the end, she is revealed as a woman and reverts to a stereotypically feminine role by marrying the king. *Silence* highlights the fact that such tales, while seeming to empower women, construct holiness or heroism in masculine terms;

► THE STORY OF ST. EUGENIA

The tale of St. Eugenia, originally composed in the eastern Mediterranean in the sixth or seventh century, is typical of the hagiographies (saints' lives) that deal with cross-dressing women. Eugenia's story was included in a number of prominent hagiographical texts, including Jacobus da Varagine's thirteenth-century *Legenda aurea* (*The Golden Legend*), a compilation of saints' lives that was translated into many vernacular languages and was beloved throughout Europe for centuries. In the tale, Eugenia is the daughter of Philip, the pagan Roman governor of Egypt. When she learns about Christianity she converts and then disguises herself as a man in order to join a monastery. The truth about her womanhood is known to the abbot, who has received a message from God, but he decides to keep her secret. Eugenia, now Eugenius, proves to be an exemplary monk, but problems arise when a wicked woman named Melanthia falls in love with Eugenius. The monk rebuffs her advances, but Melanthia spitefully accuses Eugenius of trying to seduce her. Philip himself adjudicates the case, and in order to prove her innocence Eugenia must bare her breasts. Now reunited with her estranged family, Eugenia helps them all to convert to Christianity, and they later die as martyrs for the faith.

—John William Sutton

they do not question the gender hierarchy in which the male is seen as superior. Thus, in order to better themselves, women must ape the male gender.

Female cross-dressing seems to have been accepted when women were trying to be more like men, but it was severely condemned when women used transvestism as a vehicle for challenging or usurping male authority. Consider the case of the mythic Pope Joan. According to legend, a ninth-century woman named Joan (the name varies depending on the source) took a male identity and rose through the ranks of the Church until she was elected pope and reigned for more than two years under the name John Anglicus (John the Englishman). Her womanhood was revealed graphically when she gave birth in the street to a child fathered by her

lover. In most accounts, she dies in childbirth. The earliest references to Pope Joan do not occur until centuries later, and while today it is accepted that she never existed, many throughout history have believed the story to be true. Protestant reformers referenced Pope Joan among their attacks on the Church, while the Church vehemently denied Joan's story. All sides did agree, though, that it was unthinkable for a woman to reign over Christendom. Joan of Arc (ca. 1412–1431), the most famous medieval transvestite, was another woman whose cross-dressing was condemned because of the power she wielded over men. Joan was executed for heresy because, although she had promised her captors that she would stop wearing male clothing, she relapsed and did so again, claiming that it was God's will. Ironically, by this claim, Joan herself conformed to the patriarchal belief that heroism and godliness were inherently male qualities.

Male cross-dressing, meanwhile, was rigorously persecuted. Any man who dressed as a woman was reviled for lowering his status in the gender hierarchy. Male transvestism was only allowed when it was clear that the individual was unmistakably a man. The thirteenth-century knight Ulrich von Lichtenstein, for instance, claims in his (perhaps fictionalized) autobiography that in order to honor women, he once dressed in female attire for a journey and along the way competed in several jousting matches, while so attired. Likewise, in one episode from Thomas Malory's fifteenth-century Arthurian cycle, Lancelot, fed up with another knight's constant verbal jabs, disguises himself as a woman, defeats the knight in a joust, and then forces him to wear a dress so that he can be mocked before Arthur's court.

Additionally, men and boys were permitted to dress as women to play female roles on the stage. This tradition continued in England well into the seventeenth century, decades after most other European countries had allowed women to act. This transition was resisted in England largely because of the weight of historical precedent for males playing female roles and the opposition of such actors to having women usurp their livelihood.

Gender and Sexuality—Two Spirit People in North American Indian Cultures

In many pre-contact American Indian nations, including the Klamath, Chumash, Hopi, Ojibwa, Winnebago, Crow, Cheyenne, Diné (Navajo), Ute, Papago, Teton Lakota, Oglala Lakota, and Santee Dakota, certain individuals, identified as "two spirit people," were believed to have both masculine and feminine spirits that accorded them special status in their communities. Intersexed people—or people who have a combination of male and female internal and external genitalia—were considered to be two-spirit by many cultures, as were biological males choosing to express feminine gender characteristics and biological females choosing to express masculine gender characteristics. Although some two-spirit people engaged in sexual activity that would today be considered homosexual, their positions within their communities focused on the responsibilities and privileges given to them because of their special gender expression rather than on their sexual practices.

Feminine gender roles in pre-contact North America were considered powerful positions. Native American women maintained sophisticated relationships with the plants and animals that surrounded them. Women provided food, building materials, and medicinal plants for their families. As the suppliers of more than half of the food supply and materials for trade, women played

a fundamental role in these traditional economies. Likewise, male gender roles, such as hunting, fishing, and warfare, were equally honored. Indeed, reciprocity was the principle through which relationships between sexes and genders were cultivated and refined, and through which a person's contributions to the continued existence of society were recognized.

Within this context of respect for the work performed by both women and men, two-spirit people found an honored place. Individual nations accorded unique statuses to women-men (men performing a feminine gender role) and allowed for varying degrees of flexibility. The performance of feminine tasks was noted among many California tribes, including the Chumash, Pomo, and Yurok. This included gathering food, preparing meals, weaving, and sewing. Feminine occupations for women-men also existed among the Kutenai, Klamath, Quinault, Aleut, Ojibwa, Winnebago, Crow, Cheyenne, Teton Lakota, and Santee Dakota. The Crow *boté*, the Chumash *joya*, the Cocopa *elxa*, and women-men among the Santee Dakota, Oglala Lakota, Diné, Ute, Papago, and Pomo are described as having an early proclivity for feminine tasks. Women-men in other communities performed a combination of masculine and feminine tasks.

Women-men married or had sexual relations with men or women depending on the nation. Sexual relationships between women-men and men occurred among the Crow, Yuma, Apache, Santee Dakota, Klamath, Chumash, Diné, Cheyenne, Hopi, Papago, Ute, Zuni, Pomo, and others. Scholars report sexual relationships between women-men and women among the Zuni, Diné, Papago, Crow, Klamath, Osage, and others. In some cultures women-men remained celibate, while in others they were sexually available to many. Among the Cheyenne, Chumash, Natchez, Cree, Kutenai, Crow, Papago, Yuma, and Pima, researchers noted an early preference for female company among women-men. The Lakota *winkte*, Zuni *lba'ma*, and women-men among the Santee Dakota, Osage, Hopi, Cheyenne, Diné, and the Yuki were described as speaking in a feminine manner.

Most pre-contact nations believed that two-spirit people engaging in sexual activity with each other was improper. Sex between two-spirit

people was sometimes understood to be like sex between members of the same family. In many areas the terms used for sex between males were different from those for sex between a man and a woman-man.

Man-woman status (a woman performing a masculine gender role) also allowed for flexibility in dress, work, and sexual relationships. Among the Achomawi of northern California, men-women dressed in feminine clothing but performed masculine work and married women. One Klamath man-woman assumed masculine responsibilities, including marriage, but continued to wear primarily feminine clothing. Mohave, Quinault, and Paiute men-women performed masculine tasks, wore masculine clothing, and often married women. Warfare was usually associated with men but could be performed by women and did not necessarily coincide with masculine or ambiguous gender identification. Thus female warriors were not always viewed as changing gender roles and are excellent examples of gender-role crossing without full status change. Yet in some nations, full status change was possible, as some individuals could hold two-spirit status for a period of time and then take on an exclusively masculine or feminine status.

Both women-men and men-women often had specialized roles. As historian Sabine Lang has indicated, women-men were typically healers, “gravediggers, conveyers of oral tradition and songs, and nurses during war expeditions; they foretold the future, conferred lucky names on children or adults, wove, made pottery, arranged marriages, and made feather costumes for dance.” Women-men healers were common within cultures in which female healers were prevalent. Because women-men were considered to have both masculine and feminine spirits, they were believed to have extraordinary access to the spirits and special insight into relationships between men and women. For example, the Lakota winkte had special powers symbolized by wearing women’s clothing, and much like other powerful people they carried symbols of their spirit healers in medicine bags. Feminine clothing represented connection to spiritual power, a connection so potent that medicine people approached winktes for advice.

Female Spirituality in the Americas

Prior to the arrival of Europeans, most American Indian women and men understood their roles and lives to be mutually complementary in all aspects, including spirituality. Women functioned shamanistically (that is, as intermediaries between the human and spirit world) no differently than men, and many of their ritual roles were similar. In other cases, men and women had different ritual roles that complemented one another: men often identified with a male Sky and women with a female Earth. But in all traditions for which there are relevant data, it is clear that women were understood to be spiritually more powerful than men because of several factors. Women are clearly linked to Earth in a number of significant biological ways, whereas men do not mirror Sky so directly. Women also were understood innately to connect with the spirit realm, whereas men normally needed ritual activity to enter the same trance states. While women and men had equal access to the spirit realm, men had to work harder at it.

For nearly all American Indian religious traditions, the realm of the sacred, prior to the influence of Christianity, was one of female and male complementary deities. The virtually ubiquitous tobacco offerings, whether or not in a pipe,

were invariably to the zenith and nadir, or the male Sky and female Earth, and the four cardinal directions, the order varying; the four directions represent the Four Winds, some male and some female. Female Moon is paired with male Sun (some traditions reverse the gender because of particular geographical circumstances); the male Morning Star is paired with the female Evening Star; and so forth. Associated with these cosmic deities are various animal and plant deities, gendered according to their function. Those animal spirits on which humans subsist are female; those perceived primarily for their predatory or protecting virtues are perceived as male. Hence, the black Bear, the major healing deity, was perceived as female, while the ferocious grizzly Bear was understood to be male.

Throughout North America, in gatherings for rituals such as Sacred Pipe ceremonies, it was (and is) common for women and men to sit at opposite sides of a circle; hence, they are separate, yet together they complete a sacred circle. Often, in ritual lodges, men and women take on separate, complementary roles; for example, men tend the sacred fire, and women prepare the ritual feast. In constructing Midewiwin (the Grand Medicine Society of the Ojibway tribes of the Great Lakes region) lodges and many Spirit ("sweat") Lodges, men gathered the wooden poles for the framework and women gathered boughs. Each has a different role in their construction. In summary, American Indian religions are those in which both genders have complementary, essential roles.

Women and Men in Oceania

In most of Oceania there was a bias toward tracing inheritance through the male line (patriline-

➤ AN ALMOST LOST FEMALE RITUAL PRACTICE

An important set of rituals, primarily engaged in by females, were those directly involved with foraging and gardening—women's contribution to a society's subsistence. Unfortunately, because early Western social scientists linked religion exclusively to male activities, they studiously ignored many of these foraging and gardening rituals as practiced throughout North America. The oversight was usually not deliberate; most ethnologists were just totally oblivious to them. We have detailed studies of subsistence rituals in horticultural-hunting Plains cultures that leave out the gardening rituals, and the important planting rituals of the Eastern Iroquoian-speaking peoples are simply not to be found in the ethnographic literature. The only depiction of the female aspects of these rituals is limited to Amazonian cultures, and then in only a single study.

—Jordan Paper

al descent), giving men relatively higher status than women. Since rank was so highly valued, however, in many parts of Oceania, including Hawaii and New Zealand, a kind of ambilineal descent, tracing inheritance through a line of men or women of highest rank, prevailed. Being a first-born or a later-born was often more important than one's gender in determining rank. In some cases, most famously the Trobriand Islands that lie in the Solomon Sea off New Guinea, outright matrilineal descent (whereby inheritance was traced through a line of women) dominated.

Throughout Oceania division of labor by gender was similar. Often the land and gardening were associated with women, while the sea and fishing were associated with men. Women were more likely than men to focus on tasks near home such as taking charge of child care, the daily tending of the garden, the making of tapa cloth, and clothing, weaving, and cooking. Men were more likely than women to take charge of activities farther from home such as fishing, warfare, the heavy labor of clearing the land for gardening, house and canoe building, stone tool manufacture, trade, and religious activities. Some of these divisions of labor by gender have

➤ WOMEN OF POWER IN TONGA

To suggest that in Oceania men usually had more power and status than women is to simplify the complex relationship between the genders. In Tonga, for example, where, along with Fiji and Samoa, Polynesian culture is thought to have first developed, women had an extraordinary amount of power and status, especially in chiefly families.

In Tonga a person's political rank was inherited through the father. Therefore, male chiefs passed along their chiefly positions to their sons. Social and spiritual rank, however, came from one's mother. Individual Tongans obtained their rank and place within the social order through their mothers. Among siblings, women always had more rank than men. In order to improve the rank of their children, men attempted to marry as high a ranking woman as possible.

In chiefly families the higher rank of sisters to their brothers presented a unique problem. While typically a paramount chief had more rank than anyone else in society, a chief's sisters and all their children outranked him. A chief's sisters' sons could even appropriate the chief's possessions because they outranked him. This problem was mitigated by either a chief's sisters never marrying or marrying high-ranking men from Fiji. Because of such intermarriage a chief's sisters' sons were Fijian, not Tongan, and not a threat to the chief.

—*Sharlotte Neely*

a certain logic. With greater upper-body strength, men dominated in activities requiring heavy activity such as cutting down trees to clear an area for gardening. Without child care duties, men dominated in dangerous activities such as warfare.

There were, however, significant deviations from these routines throughout Oceania. In the

highlands of New Guinea, for example, men rather than women typically did the weaving. In Hawaii men did the cooking, mainly because it was believed that men's greater spirit (*mana*) could be corrupted by eating food cooked by women.

Among some groups the activities of men and women were strictly segregated. In Hawaii, for example, men and women never ate meals together. In the Trobriand Islands, where premarital sex was more than tolerated, unmarried teenagers of the opposite sex could not eat together.

Nowhere was the distinction between men and women more obvious than in the area of religion, where men dominated. In the highlands of New Guinea men were responsible for building the ghost houses to divert the spirits of the dead away from the living. In the Trobriand Islands the magical practices that made food grow, canoe trips safe, and life in general good were performed by men. Temple building in Polynesia was done by men and was such important work that high-ranking chiefs labored alongside commoners. In Hawaii, as elsewhere, priests were men and were typically believed to possess greater *mana* than women. A first-born woman from a chiefly family, however, might outrank almost every man.

■ Introduction: Centers of Religious and Secular Learning—Were the Great Academies Outside of Europe Universities?

Culture is passed from one generation to another through a variety of media. In its most basic form, it is through example and instruction imparted by parents to their children. In preliterate societies it also consists of elders, and not necessarily blood relatives, training boys and girls in traditions that are deemed critical for a community's well-being. Since the dawn of civilization, literate sedentary societies have instituted formal schools for the education of future leaders and those who serve the society in specialized capacities. During the period 1000–1500, education of this last sort grew in quality and quantity across the globe.

The most dramatic development, which would become a global phenomenon well after 1500, was the rise of universities in Western Europe during the twelfth and thirteenth centuries. The Latin term *universitas* means “a corporation” or “a community.” It came to be applied to institutions of higher learning in Europe that were legally recognized communities of masters and students (*universitates magistrorum et scholarium*), that offered multiyear instruction according to a set curriculum, and that awarded degrees, or teaching licenses, in both the Seven Liberal Arts and in at least one of the advanced faculties, or disciplines, of theology, ecclesiastical canon law, Roman civil law, and medicine. To achieve such degrees, students had to navigate successfully through a series of lecture courses and examinations.

Such schools originated in Italy and France, but by the year 1500 Latin Europe counted slightly more than 50 universities, each charted by an ecclesiastical or secular authority (and in some cases both), that were located from Scotland and Portugal in the west to Sweden in the north and Hungary and Poland in the east. Most universities attracted professors (as they were also known) and students from all over the Christian West, but despite the fact that they spoke a variety of native languages, church Latin was their common tongue and the language for all instruction and testing. Thus, Paris's left bank

of the Seine, where its university was located, became known as the Latin Quarter.

As the various entries under this topic illustrate, educational institutions that offered a complex array of primary, secondary, and advanced instruction proliferated in number and tended to grow in size around the world during this half millennium. Given this fact, it has become fashionable in some circles to bestow the title of “university” on some of these large multidisciplinary academies, such as the three madrasas at Timbuktu in the empire of Mali that have often been cumulatively referred to as a university or the fourteenth-century Madrasa of Sultan Hassan in Cairo, which offered instruction in all four schools of Islamic jurisprudence. There is no denying that these and many other madrasas throughout Dar al-Islam were spiritual and intellectual centers that offered instruction in a wide variety of fields, both religious and secular. But they were not universities in the sense of European universities, which, as noted, offered set curricula and academic decrees for the successful completion of formally established academic programs. These schools, such as thirteenth-century Oxford and Cambridge, and only these schools, were the progenitors of modern universities.

Whereas European universities were proliferating and becoming an increasingly important element in the Latin West's intellectual, social, and economic life, the same was not universally true for Buddhist monastic academies. Ceylon, Japan, Tibet, Mongolia, and Southeast Asia witnessed a growth in the numbers and size of Buddhist monasteries, but this was not the case in Central Asia, India, and China, where wars, raids, and the surge of Islam (in Central Asia and northern India) brought in their wake the destruction of numerous ancient Buddhist centers of devotion and learning and a clear and sharp diminution of their religious and educational significance. A case in point was the monastic complex of Nalanda in Bihar, India. This monastery, which has been characterized as “one of the first great universities in the world,” was a center of advanced

study in a wide variety of Buddhist and Hindu religious traditions, as well as secular subjects since at least the fifth century CE. The great seventh-century Chinese pilgrim-monk Xuanzang had studied and taught there, and over the centuries the monastery's fame as a center of piety and scholarship attracted Buddhists from all over Asia. In the last decade of the twelfth century the monastery was destroyed by Turkic Muslim raiders, a sad but fitting symbol of the rapid decline of Buddhism in the land of its origin.

Nalanda has remained in ruins to this day, although there is serious discussion of building on its site Nalanda International University, a graduate-level research university. When and if Nalanda rises again, much of its curriculum will focus on Buddhist subjects and on issues of special significance to contemporary Buddhism, such as peace and environmental ecology. But there are also plans to incorporate within it a School of Business Management and Development. This new institution with an ancient name will undoubtedly follow the model of what was once an exclusively European form of institutionalized instruction but is now international, the degree-granting university.

—*Alfred J. Andrea*

The Madrasas of Islam

The *madrasa* is the archetypal school of Islamic religious sciences, which include such studies as Sharia (religious law), quranic exegesis, theology, and hadith (the sayings of the Prophet), all taught systematically from secondary to a higher level following a youth's *kuttab* (primary) education. Madrasas have traditionally been given the task of maintaining Islam's ideal religious orientation and during the period 1000–1500 could be found from Spain and western North Africa to China in the east and sub-Saharan Africa in the south but were largely concentrated in the Islamic heartland, the so-called Middle East. The word “madrasa”—romanized as *medrese* in Turkish and Persian due to the phonetics of these languages—derives from *darasa*, a generic place where the acts of “reading, understanding, learning, and memorizing by repetition” take place.

The madrasa went through certain phases of development as it evolved to become a long-

lasting, discrete center of learning. In the first phase, the mosque functioned as an instructional core by concentrating primarily on the sacred texts and scriptures, which were learned by heart, thereby inculcating an understanding of the Quran in the early Muslim community at the time of the Prophet in Medina (622–632) and for at least the rest of the century. Muslim students traveled extensively to seek knowledge and learn from prominent teachers, and teachers also traveled about, searching for opportunities to teach and to learn from others by discussing and exchanging ideas with scholars in distant lands. In so doing, they were following the strictures of one early hadith, or saying, ascribed to the Prophet: “Seek knowledge even if it is in China.” The *jami-khan* (inn at the mosque) complex emerged naturally in the second phase, when the khan (inn) was built next to the jami (mosque) around the eighth century and served as a lodging place for students who came from remote areas. The third phase, which occurred around the eleventh century, witnessed the madrasa as an independent institution of learning, primarily in religious studies but expanding sometimes to other fields of knowledge, such as medicine and astronomy. Both prior to the emergence of the madrasa and after, Muslim education, as it had been from earliest days, was a characteristically personal and informal affair, and thus as the madrasa began to develop, the jami still continued to function as a school as in the past, centering on basic religious studies and sometimes on Islamic studies. Indeed, there was a good deal of intersection between madrasas and jamis for quite a while.

In 1067 Nizam al-Mulk, the great vizier (1064–1092) of the Seljuk sultans Alp Arslan and Malik Shah, established the Madrasa Nizamiya, named after him, in Baghdad in order to confront intellectually and to dismantle Shia teachings in the region. This institution marked a turning point in the history of madrasas, as it became one of the greatest educational foundations of higher learning in the Muslim world. Endowing scholarships for the students and attracting many leading scholars to teach, his model of a madrasa immediately spread throughout Iraq and into Khurasan and other neighboring regions.

Madrasas were essentially charitable institutions based on a deed of trust (*wakf*). As the founder was free to establish any type of organization or project, he or she was also free to determine the subject matter and books to be taught in the newly established madrasa as long as neither violated the tenets of Islam. Therefore, the deed of a foundation contains significant information about the curriculum and the teachers and students. According to the deed of foundation of Altun-aba Madrasa, for instance, written in 1202 in Konya in Anatolia, this madrasa accommodated three groups of students (from beginners to higher levels) along with a professor (*mudarris*), his assistant (*muid*), an imam (prayer leader), and other supporting staff and custodians. The *wakf* of the madrasa also outlines how much a professor, students in the varying levels, and the whole staff would get paid and how much should be spent on buying books annually. It even tells us when the madrasa had the right to expel a student (apparently it expelled a student if he failed at the end of the fifth year).

Madrasas were generally established to teach one or more of the four major schools of Islamic juristic thought (*fiqh*). In some instances during this period all four would be taught in a single madrasa but in separate classes. Although many different subjects, ranging from the traditional religious disciplines to logic and literature, were taught in madrasas, philosophical subjects were not always in their curricula and were sometimes disparaged and excluded. All subjects, however, were taught in an integrative style, supplementing one another. Linguistic sciences, for instance, were taught in relation to the study of the Quran and hadith, and mathematical subjects were taught in relation with the musical theory of tones (*al-musiki*).

As was also the case in the universities of Latin Europe at the time, lecturing and learning by heart were generally the basic method of instruction in madrasas. Dictation (*imla*) was slow and methodic, as the students wrote down the lectures, usually verbatim. Then, students usually quizzed one another to foster their learning and comprehension of the subject in question, whereby the concept of *mudhakara* (“a calling something to mind with another”; “conferring

➤ THE OTTOMAN SAHN-I SEMAN MADRASAS

The Sahn-ı Sema Madrasas were established by Sultan Mehmed II inside the complex named after him (Fatih Külliyesi) between 1463 and 1470 in Istanbul to provide higher education in both Islamic disciplines and the rational sciences at the most advanced level. All madrasas in the complex were divided into *Semâniye* (higher level) and *Tetimme* (secondary level), with each Tetimme madrasa leading to a corresponding higher level of Semâniye madrasa. Although it is known from the deed of trust of Semâniye and also from the practice until the end of the sixteenth century that both Islamic disciplines and rational sciences were taught integratively, the prominent Ottoman traveler Evliya Çelebi said that these madrasas were opened only to teach religious knowledge. In the seventeenth century, Çelebi described these madrasas as follows:

“There are eight madrasas on the right and left side of Sultan Mehmed Han mosque, . . . which are called ‘semâni madrasas’ by scholars. [Mehmed II] constructed these eight madrasas looking like heaven in the world to revere and encourage religious knowledge, and honor the people of knowledge (*Ulemâ*). Each garden of a madrasa turns into a garden in heaven with the signboard of knowledge. This place has fairly high esteem among the *Ulemâ*. . . . There is a hospital on the eastern part of the madrasas for sick, poor and wretched people, and a large kitchen covered by seventy domes that serves generously for the needy.”

Orhan Şaik Gökyay, *Evliya Çelebi Seyahatnâmesi*, Vol. 1 (İstanbul: Yapı Kredi Yayınları, 1995), 129. Translated by author.

with another”) developed. The most significant and innovative method developed in madrasa education, especially in legal studies, was the process of disputation (*munazara*), which was comprised of a systematic knowledge of divergent legal opinions on the matter and a thorough knowledge of dialectic and the skill of disputation. This very much paralleled a similar form

of disputation that was then prevalent in the universities of Latin Europe from the twelfth century onward. Although there were many points of contact and interaction between Europe and the Muslim world through Sicily and al-Andalus (Muslim Spain), it would be hard to prove if one influenced the other, but it is not inconceivable.

Starting from the eleventh century, madrasas were usually located within the complex of the larger mosques. There they included classrooms, a prayer hall, kitchens, lodging places, and, more importantly, libraries, where books were gradually collected from gifts and bequests, especially donated by local scholars whose common habit was to give their books for the use of seekers of knowledge. Although there was a great deal of variation in the design of madrasas, the distinctive construction of a madrasa was a square, of one or two stories, encircled by a courtyard. These educational institutions also hired scribal personnel, such as a copier, a stationer, a proof-reader, and a bookbinder, to meet their instructional needs. In large madrasas, such as the Mustansiriyyah in thirteenth-century Baghdad or the Süleymaniye in sixteenth-century Constantinople/Istanbul, subjects such as medicine, mathematics, and astronomy were taught within the same complex as religious disciplines.

It would be erroneous to imagine the madrasas as a monolithic entity or as unchanging, static, frozen schools unaffected by the sociocultural, religious, and political changes that surrounded them. As Islamic schools of law varied according to geographical and cultural settings and from one era to another, so did the curricula of the madrasas, although instructional modification was not always significant or obvious.

Islamic Book Production

The production of luxury books, featuring increasingly exquisite levels of calligraphy, illumination, illustration, and binding, was strongly supported across the Islamic world between circa 1000 and 1500. This apparently elite pursuit nonetheless sustained the composition and preservation of classic texts in all branches of learning and literature, mirroring the vigor of a wider intellectual community. Already by the year 1000, famous libraries with holdings of many thousands of volumes were accumulated by bibliophile collectors, both rulers and civilian elite, in cities across the Islamic world such as Umayyad Córdoba, Fatimid Cairo, Abbasid Baghdad, and Buyid Shiraz. These libraries were accessible to private scholars, and some even provided facilities for visitors to make their own fresh copies from older exemplars on the shelves, with ink, paper, and even copyists made available. Books were therefore produced at different levels of expense but to similar ends: as trophies of cultural refinement and ambition and as sources of intellectual life.

The arrival of paper technology from western Central Asia and ultimately from China in the eighth century supported wider book production considerably as did calligraphic reforms, which improved legibility and the connoisseurial appreciation of Arabic script. While book culture was well established by the year 1000, this point marks two historical milestones: one of the earliest extant Quran manuscripts to be written on paper (dated 1000–1001), copied in Baghdad by master calligrapher Ibn al-Bawwab, and also the first extant illustrated book in Islamic art, a copy of al-Sufi's *Book of Constellations* (dated 1009–1010), copied and beautifully illustrated by the

astronomer's son possibly in Rayy, Iran. Earlier anecdotes and tantalizing fragments bespeak the currency of illustrated books before this, but extant examples of manuscript painting survive with increasing frequency only from the later twelfth century onward, attributed to Iraq, Syria, and Anatolia. These works cover an impressive range of subject matter: astronomy, medicine, zoology, pharmacy, botany, and mechanical literature of both classical Greek and Islamic-world authorship, along with works of Arabic *adab* (elegant literature), such as the *Kitab al-aghani* (*Book of Songs*) and the *Maqamat* (*The Assemblies*).

The illustrations are didactic or narrative, depending on the character of the original text, but conditions of composition and patronage are laid out in the frontispiece, usually a full-page painting in the opening pages, portraying the major contributors to the book's production. Initially this privilege was reserved for the author himself and is a late classical inheritance. Increasingly, the princely patron was included to the eventual exclusion of the original author. By the Timurid period (late fourteenth–fifteenth centuries in western Central Asia), the frontispiece painting typically delivers a portrait of a royal patron at leisure, reading among friends in an intimate garden setting and attended by servants and musicians. This describes the illustrated book as a treasured possession in its most elite context. Until the Persian Il-khanid period (late thirteenth century to the 1330s), it is difficult to make traditional art-historical attributions of manuscript paintings to any particular court or dynasty, with rare exceptions. Several twelfth- and thirteenth-century illustrated manuscripts specify that they were produced for private citizens or do not overtly proclaim any patron royal or otherwise, implying speculative production for the open market. Certainly, there was a lively economy in this trade, as books old and new were marketed to the interested public from the *sug al-warraqin* (stationer's market) in all major cities.

From the early fourteenth century, princely libraries and/or associated workshops (*kitabkhana*) served as exclusive production centers where teams of craftsmen contributed to the

➤ CAIRO—CITY OF SCHOLARS

In 969, the Fatimid army established a new capital in Cairo, on behalf of the Ismaili caliphate. Just northeast of the wealthy commercial quarter of Fustat, the Fatimid caliphs built a new palatine precinct named al-Qahira (the Victorious), where the Eastern and Western Palaces, gardens, army barracks, and ceremonial mosques were located, with monumental gateways set around the perimeter. Political propaganda underlay the ambitious architectural glamour: the majesty of (Ismaili Shia) Fatimid Cairo was an open challenge to metropolitan Baghdad, where the (Sunni) Abbasid caliphate was based. Perhaps in the same vein was the Fatimid policy regarding the support and advancement of learning: Cairo became a renowned center of scholarship and teaching for classical Greek sciences as well as Ismaili theology at grand public libraries as well as mosques, such as al-Azhar. In 1005, Caliph al-Hakim (r. 996–1021) founded the prestigious Dar al-hikma (House of Wisdom), at the Western Palace. This scholarly institution had teaching facilities for astronomy, mathematics, and medicine and also had an open-access library, with many volumes contributed from al-Hakim's considerable personal collection. The foundation document stipulates an annual budget to be spent on paper, ink, and pens for visiting readers as well as the upkeep of the bookbindings, provision of carpets during winter, and the librarian's salary.

The termination of the Fatimid caliphate in 1171, with Saladin's restoration of Sunnism in Egypt, caused many of the great Cairo libraries to be broken up. Ismaili texts regarded as heretical were destroyed, while works on classical sciences were sold off or claimed by bibliophiles in the new administration for their own collections.

—Moya Carey

design and execution of luxury books: Il-Khanid Tabriz, Jalayirid Baghdad, and Timurid centers in Samarkand, Shiraz, and above all Herat. The remarkable *Arzadasht* progress report (ca. 1430), apparently written by the *kitabkhana* director of Timurid prince Baysunghur in Herat, describes several ongoing projects, from designs for leatherwork to book illustration, and details the contributions of individual painters and calligraphers

as well as any setbacks encountered, including poor health.

The model of an ideal ruler was attached firmly to cultural sophistication, and princes were usually keen to sponsor intellectual and artistic life at court, either by welcoming poets and scholars or by commissioning new copies of classic texts. The best example of this is the enduring meaning of the *Shahnama* (*Book of Kings*), the Iranian national epic composed around 1000 by the poet Firdausi. From the Ilkhanid period forward, remarkable illustrated copies were commissioned by all rulers aspiring to Iranian kingship; having one's personal copy has been characterized as a "touchstone of royalty." Books therefore had political meaning as well as cultural value in the Islamic world; they were collected, treasured, consulted, and reproduced at different levels of a society with an enduring bibliophile culture.

Formal Education in Southeast Asia

Prior to European contact, Southeast Asia had strongly developed traditions of literacy and formal education. These traditions were built upon the region's diverse religious and cultural heritage and the Hindu, Buddhist, and Islamic institutions integral to the local societies. Buddhism, largely of the Theravada variety, with an educational system based on the monasteries, was firmly established in lands that today are the nations of Myanmar (Burma), Thailand, Laos, and Cambodia. Islamic schools existed in Malaysia, Brunei, and Indonesia. In northern Vietnam, Confucian principles derived from China underpinned a highly systematized pattern of education, and Mahayana Buddhist monasteries provided education in southern Vietnam. Only in the Philippines is there little evidence of a tradition of religious education.

Religious education in Southeast Asia's Buddhist societies was provided by monks attached to monasteries. The first stage of education was a prerequisite for young men to be ordained as monks, an important rite of passage in these societies for most males, even those who had no intention of becoming monks for life. Typically, at the age of five or six boys were sent to the local monastery, where monks taught them to read religious texts, do simple arithmetic, and learn religious principles. The instruction was individualized, as a monk would have no more than 10 or 12 pupils, each working through his lessons at his own pace. Usually there was no specific curriculum or formal examination, although there was progression through texts and tasks. Boys were free to come and go as they wished from the classes.

Most young men trained in the monasteries did not continue their formal education past or-

► FAMILY-BASED EDUCATION

It is impossible to determine precisely to what extent formal religious education touched the lives of children in premodern Southeast Asia, especially in its more remote areas. Family-based education provided the skills needed for daily agricultural and domestic life and was probably the most common form of education available to boys as well as girls throughout traditional Southeast Asia. In those regions where animism was the major form of religious and spiritual belief, education could also include apprenticeships in shamanistic practices, magic, and sorcery.

—Christine Inglis

dination into the *sangha*, or monastic community. This included the minority who remained in the monastery for life and the vast majority who were part of the ordained community for only a few years or less before returning to the outside world, where they would marry and pursue secular lives. Although they had gained some secular knowledge, the main purpose of this system was to gain a moral education that properly situated them within both the monastery and, if they returned to the outside world, the larger Buddhist community. The system did, however, provide an avenue of social mobility for young men from poorer backgrounds.

Because this type of learning was a religious act, monastic education was common among young men, but girls were excluded from it. If they learned to read or write, it was either at home from members of the family or, for girls from elite families, with a tutor.

Rhetoric and Education in Byzantium

The Byzantine empire inherited its educational and literary culture from the Hellenistic world and late ancient Christianity, and these traditions were fundamental to its thought, expression, and intellectual life. Far more than Western Europe, Byzantium remained a literate society where civic and church officials were expected

to be educated and able to write in a literary prose style and where classical as well as Christian texts were studied. Elementary and secondary education took place in private schools, where Hellenistic Greek language, grammar, and rhetoric were taught, and students prepared for civil service. Higher education sponsored by the state was revived in the eleventh century in Constantinople, including the study of law and philosophy, and theology was studied in a Patriarchal Academy. In both spheres, classical writers such as Plato, Aristotle, Homer, and the Greek tragedians as well as Christian theologians were read. Students mastered grammar and style through specially composed passages (*schedographia*) and interpreted and debated these texts, posing problems themselves, and by the eleventh and twelfth centuries intellectual circles knew, analyzed, and imitated a large body of classical and Hellenistic learning.

The ancient rhetorical tradition was the most important influence on Byzantine literary culture. Oratory was an essential part of public life in antiquity, where rhetoric included not only the ability to speak effectively with persuasive words but also the ideas and moral issues conveyed. Byzantine rhetoric preserved the tradition of virtuoso speeches given for praise (panegyric), information (*ekphrasis*), or blame (invective). The rules of rhetoric were learned from handbooks by Hermogenes, Menander, and Aphthonius, written from the second to fourth centuries CE, that spelled out the elements of prose (*progymnasmata*). These became the basis not only for Byzantine speeches but also for literary prose of all kinds, from history to saints' lives and military manuals.

Professional oratory survived throughout the Byzantine empire. It was performed by rhetors in settings that ranged from weddings and funerals to inaugural addresses and annual encomia in aristocratic homes, churches, tombs of saints, and the streets of Constantinople. Speeches were part of theatrical occasions that could include music, dance, and processions in what has been described as the Byzantine media. Most important were the panegyrics given by the imperially appointed master of rhetoric on ceremonial occasions. Rhetorical texts, filled with literary conceits and difficult to understand, were written

➤ MICHAEL PSELLUS

Michael Psellus (ca.1018–ca.1081), one of the leading intellectuals in eleventh-century Byzantium, epitomized the importance of learning and rhetoric in this era. Although his family was not wealthy, he was educated by a leading scholar and became a member of a circle of influential intellectuals. As court philosopher, Psellus served as a tutor or adviser to emperors. A wide-ranging scholar, his prolific writings included works of philosophy, theology, rhetoric, law, and history. Psellus's most famous work, the *Chronographia*, offers vivid portraits of the emperors from Basil II (r. 976–1025) to Michael VII (r. 1071–1078). Psellus saw the traumatic events of the eleventh century as a result of imperial character rather than of divine will or fate, and he emphasized the strengths and weaknesses of each ruler, generally from firsthand observation. His brilliant portrayals of the empresses Zoe and Theodora and Constantine IX Monomachus (1042–55) give an unmatched view of court life and politics.

—Dorothy de F. Abrahamse

down after the performance and today give little understanding of what the overall experience would have been. But when read carefully, they demonstrate political themes and even veiled satire.

Rhetoric and its classical antecedents permeated Byzantine intellectual culture. Its language was that of classical antiquity and was quite separate from the spoken Greek of the streets. The use of ancient models led historians to identify, for example, all northern peoples as Scythians (Indo-Aryan nomads from Central Asia whom the Greeks encountered around the Black Sea in the sixth and fifth centuries BCE) and to construct their narratives by the principles enunciated in the rhetorical handbooks of late antiquity. Only by analyzing the rhetorical underpinnings of Byzantine literature can it be understood and appreciated.

Byzantine Scholars in Renaissance Italy

As the Ottoman Turks completed their encirclement of Constantinople in the late fourteenth century, a succession of scholars began to flee the Byzantine empire for Italy. Over the next century, as the last vestiges of the empire were overrun, these scholars were responsible for a flowering of Greek culture in the Latin West that broadened the scope and agenda of Italian humanism. They brought with them new manuscripts of the literary treasures of Greek antiquity, both pagan and Christian, and the intellectual tools for their interpretation and assimilation.

From the earliest days of the Renaissance, Italian humanists had been aware that they needed to read Greek texts in the original in order to round out their conception of antiquity. But it was not until the very end of the fourteenth century that Coluccio Salutati, the humanist chancellor of Florence, succeeded in lobbying his state to hire Manuel Chrysolaras as a teacher of Greek at the University of Florence. Although Chrysolaras only remained in Florence from 1397 to 1400, the effect of his sojourn was remarkable. He trained a generation of Italian scholars in Greek, including such luminaries as Leonardo Bruni, and in so doing helped broaden the scope of humanism. Chrysolaras also introduced his students to a new theory of translation that stressed the importance of rendering a readable text that retained the sense and spirit of the original. While he was in Florence, Chrysolaras was invited by Giangaleazzo Visconti to come to teach in Pavia. Although Chrysolaras was loath to go, the Byzantine emperor implored him to do so, for the emperor hoped that by nurturing Western interest in the culture of Greek antiquity he

➤ CARDINAL BESSARION

Cardinal Bessarion by Joos (Justus) van Ghent, fifteenth century. (Erich Lessing/Art Resource, NY)

In the preface to his translation of *Thucydides*, Lorenzo Valla famously described Cardinal Bessarion as the “most Latin among the Greeks and the most Greek among the Latins.” While certainly an exaggeration, Valla’s comment reflects the profound contribution that Bessarion made to the preservation of classical Greek learning and its assimilation into Renaissance scholarship.

Born in 1403 in Trebizond on the Black Sea and educated in Constantinople, at age 20 Basil Bessarion became a monk of the Order of St. Basil and later was ordained a priest. In 1438, he traveled to Italy as part of the emperor’s delegation to the Council of Ferrara-Florence and despite his youth gave the first address to the council on behalf of the Byzantine Orthodox party. At the

council, Bessarion worked hard to foster union between the two branches of the faith, eventually proposing a compromise position over the *filioque* controversy that opened the door to the union that was proclaimed in July 1439.

Almost immediately upon Bessarion’s return home in 1439, word reached him that he had been proclaimed a cardinal in the Roman Church, at which point he immediately returned to Italy. There, and for the rest of his life, Bessarion saw his role as twofold. He wanted to organize a crusade against the Turks and, especially after the capture of Constantinople in 1453, preserve as much of the intellectual heritage of classical Greece in the West as he could, until such time as it could be returned to its homeland. Although his crusading efforts led to naught, Bessarion became a focal point for Greek studies in Italy. He was a patron to many Greek émigré scholars, encouraging their work as translators of Greek texts and even sending them into the former lands of the Byzantine empire to copy or acquire more manuscripts of classical texts on his behalf. By his death in 1472, Bessarion had acquired one of the largest private libraries in Europe, comprising 746 manuscripts, 482 of which were Greek. This he left to Venice, where it came to form the heart of the *Biblioteca Marciana* in the middle of the next century.

—Richard Raiswell

might be able to arouse Latin support for the plight of his empire.

After Chrysolaras returned home in 1403, his legacy in Italy was taken up by George of Trebizond. Despite his name, George was actually born in the Venetian colony of Crete. However, finding few opportunities for a literary career on the island, he immigrated to Venice around 1420. As a scholar, he made his reputation with a rhetorical manual he penned in 1434. While manuals of rhetoric were always popular with humanists, George’s text was unique in that he tried to fuse Latin rhetorical theory with the hitherto largely unknown Byzantine tradition. The result was a Renaissance classic that offered Italian humanists a new and productive means of interpreting the literature of antiquity.

Despite the growing awareness of the cultural legacy of ancient Greece, a major stumbling block to Western aid for the Byzantine rump state in the early fifteenth century centered on religion, namely the Greek refusal to accept papal primacy, as well as certain theological issues, such as *filioque*. But with the Turkish threat becoming ever more acute, in 1438 the emperor agreed to attend a council in Ferrara that would negotiate the terms of union between the two churches. While the presence of so many Greek scholars in northern Italy for 18 months was important in itself, outside the council the major talking point came over a lecture given by Gemistus Pletho, a Byzantine Neoplatonist, on the differences between Aristotle and Plato. To many Italian humanists, Pletho’s assessment of Platonism

along with the 1469 *Against the Detractor of Plato*, written by Cardinal Bessarion, a former Byzantine Orthodox monk turned Catholic prelate, opened the door to the assimilation of the Platonic corpus, giving them a comprehensive philosophical alternative to the scholastic Aristotelianism of the universities.

From the middle years of the century, the flow of émigré scholars to Italy grew larger. Many of these men supported themselves as teachers, scribes, and translators. Indeed, Pope Nicholas V personally retained a number of Greek scholars who specialized in the translation of technical scientific and philosophical texts into Latin. In the decades after the 1453 capture of Constantinople, some scholars were employed by wealthy humanists, such as Lorenzo de' Medici, to comb the lands of the former empire to recover more manuscripts of antique Greek texts. And with the establishment of Aldus Manutius's printing press in Venice toward the end of the century, some were able to secure employment proofreading and copyediting Greek texts. In this way, then, the contribution of Byzantine scholars to the content, form, and direction of quattrocento (fifteenth-century) humanism was profound. Not only did they reorient the trajectory of the Italian Renaissance, but they also created a climate in Italy that fostered the preservation of the intellectual heritage of classical Greece.

Intellectual Patronage by the Early Ottomans

As a frontier principality in northwestern Anatolia, the Ottoman sultanate was rooted in a rich

tradition of courtly patronage of art and scholarship, which the early Ottoman sultans seem to have embraced for reasons related to Ottoman self-image and political legitimacy. Having been acculturated within the same sociocultural milieu as previous and contemporary Muslim dynasties in Anatolia and the Middle East, the early Ottomans appreciated intellectual patronage as the etiquette of royalty and sought scholars and scholarship in order to make a case for their dynasty in the ideological war over legitimacy among competing dynasties and polities (Mongol, Turkic, Mamluk) spanning from Central Asia to Russia, the Middle East, and Egypt. The engagement of the Ottoman sultans with both their heritage and their political environment commenced a trend of successful intellectual patronage through which poets, artists, and scholars filled bureaucratic positions and frequently served as counselors, physicians, and astrologers to the sultans.

Scant evidence about the dawn of the Ottoman sultanate notwithstanding, we know that Orhan integrated jurists into his bureaucratic hierarchy by appointing them as judges (*qadis*) and oversaw the opening of the first Ottoman *medrese* (an institution for advanced education) in 1331 in Iznik (Nicaea). Under succeeding sultans, major centers of the Ottoman sultanate were ornamented with advanced medrese complexes, thanks to sultanic patronage and charitable foundations mushrooming throughout Ottoman territories. From 1425 onward, the office of *şeyhülislam* (chief jurisconsult) came to represent the administration of education and the judiciary, and medreses emerged as an essential part of the Ottoman administrative system, which demanded more graduates at an ever-increasing pace. By the sixteenth century, there were in most major Ottoman cities alone more than 115 medreses.

The Ottomans knew that hosting and patronizing scholars of stature, especially if transferred from other regions, projected an image of success, prosperity, and legitimacy. Ottoman sultans actively recruited scholars of renown and encouraged the circulation of scholars and scholarship by facilitating the means of travel and education. An example of such Ottoman efforts can be seen in the recruitment of Molla Gürani

(1416–1488), a scholar serving under the Mamluks in Egypt. He was introduced to Murad II (r. 1421–1444 and 1446–1451) by an Anatolian scholar and soon was appointed as the teacher of Prince Mehmed, who would become Mehmed II (r. 1444–1446 and 1451–1481). Similarly the Italian Jewish physician Giacomo di Gaeta, after serving Murad II, continued to serve Mehmed II as his private physician. Of course, the opposite was also true; rival dynasties competed for the patronage of skilled scholars, as is the case with the would-be first chief jurisconsult Molla Fenari (d. 1431) over whom the Ottoman Bayezid I (r. 1389–1402) and Murad II and the Karamanid Alaeddin Ali and Mehmed Bey competed. Although Molla Fenari eventually returned to Bursa, he served more than a decade under Karamanid rule.

The funding, compensation, and privileges offered to scholars and artists were substantial enough to encourage education and stimulate social and regional mobility. Scholars were considered part of the ruling class and were given tax exemptions that extended to their progeny. An early example is that of Molla Fenari's sons and grandsons, who were appointed as medrese teachers and given a luxurious daily compensation of 40 golden akçes. As incentives such as this became more common and widespread, aspirants for a better life embarked on education and soon realized the importance of holding on to their privileges. This realization led to the emergence of scholarly dynasties through a process of handing down knowledge from father to son and through family relations, which created a wide scholarly-class network.

Perhaps Mehmed II epitomizes the culmination of early Ottoman achievements in many respects, including intellectual patronage. He is known to have built a palace library housing books in Latin and Greek. Credit must be given to him for commissioning and overseeing the construction and operation of the famous Sahn-ı Seman Medrese at the Fatih Mosque in Istanbul, which set an example for subsequent medreses, and for organizing the education and educational bureaucracy and codifying the regulations governing educational system in sultanic laws (*kanunnames*). The demarcations among the three major branches of the sultanate's administration—

Fatih Mosque in present-day Istanbul, Turkey housed the Sahn-ı Seman Medrese. Both were commissioned by the Ottoman sultan Mehmed II in the fifteenth century. Photograph from about 1900. (Library of Congress)

➤ THE COURT OF MEHMED II

According to Zorzo Dolfin's fifteenth-century *Chronicle*, an eye witness, Giacomo de' Languschi, had this to say about Mehmed II:

"The sovereign, the Grand Turk Mehmed Bey, is a youth of twenty-six. . . . Daily he has Roman and other historical works read to him by a companion named Criaco of Ancona and another Italian. He has them read Laertius, Herodotus, Livy, Quintus Curtius, the chronicles of the popes, the emperors, the kings of France, and the Lombards. He speaks three languages, Turkish, Greek, and Slavic. He is at great pains to learn the geography of Italy and to inform himself of the places where Anchises and Aeneas and Antenor landed, where the seat of the pope is and that of the emperor, and how many kingdoms there are in Europe. He possesses a map of Europe with the countries and provinces. He learns of nothing with greater interest and enthusiasm than the geography of the world and military affairs; he burns with desire to dominate; he is a shrewd investigator of conditions."

ilmiye (education), *kalemiye* (chancery), and *seyfiye* (army)—and the rules for each began to emerge during his reign. Mehmed II was an enthusiastic sponsor of scholars and artists, Muslim and non-Muslim alike, from faraway places, as is indicated in his portrait by the Italian Gentile Bellini; his private physician, the Jewish Italian Giacomo di Gaeta; his spiritual mentor, the Damascene Akşemseddin; his mentor, the Egyptian Molla Gürani; and the mathematician Ali Kuşçu of Samarqand.

The Origins and Nature of European Universities

The medieval European university was a unique institution in terms of organization, methods of instruction, degrees offered, and privileges. Several factors coalesced in the eleventh and twelfth centuries that had an impact on the rise of the Latin West's universities, including the Gregorian Reform Movement, which was the struggle of the papacy to reform the Church and free itself from the control of secular rulers; Europe's recovery of Roman Law; the growth of towns and international trade; expanding civil and ecclesiastical bureaucracies; and the need for lawyers and notaries in those bureaucracies. Moreover, Western Christendom's recovery of Aristotelian works created the need for it to assimilate and respond to Aristotle's thought and that of his Jewish and Arab commentators.

A common medieval term for a university was *studium generale*, which signified the ability of a school to draw students from all over Europe, and another of their special qualities was indicated by a second term associated with them, *universitas*, the Roman legal term for a corporation, or guild, of professionals within a certain field or craft. Universities were organized either as guilds of masters (such as Paris and Oxford) or of advanced students (such as Bologna). As such, they had the right to set academic standards and to recognize levels of proficiency, which became known as degrees. Those who reached the degree of master were granted a license to teach.

Although exact foundation dates are unknown, the first known university to develop in the twelfth century was Bologna, followed by Paris and then Oxford. As Europe's seminal universities, Bologna became the model, in terms of organization, for universities south of the Alps, and Paris became the model for those north of the Alps. By the year 1500 there were at least 50 universities throughout Europe.

The origins of Europe's earliest universities are somewhat shrouded in mystery. Some of the earliest universities rose almost imperceptibly (at least to us) out of cathedral schools that initially served to train local clerics. Eventually, however, these once-modest and now-famous and important schools eventually received official rec-

Library of the University of Bologna, Italy. At its height in the twelfth and thirteenth centuries, the university was one of the earliest and most esteemed in Europe. (Kelly Borsheim)

ognition through papal statutes and royal or imperial charters that confirmed their status and special privileges as *studia generalia*. For example, the emperor Frederick I Barbarossa issued *Authentica habita* in 1158 affirming the status of Bologna, and King Philip II of France chartered Paris in 1200, followed by papal recognition around 1209, 1215, and 1231; a papal legate issued statutes to Oxford around 1215 confirming the status of the masters and the school. Unlike modern universities, each of Europe's first universities received several grants of recognition and privileges over time and often from competing kings and popes, not just one foundation charter that was meant to cover every anticipated situation. Although most early universities were religious foundations, as guilds they strove to become independent of local civil and ecclesiastical authorities, usually by obtaining privileges from kings, emperors, and popes, as noted above. Once these privileges were obtained, the university had a great deal to say about curricular matters, the cost of food and rents, and anything else the students required. As clerics the students were exempt from civil courts, which meant that the rowdiness of youth often went unpunished, and bloody town-gown battles became a problem. In return for these privileges, universities provided qualified men, usually lawyers, for positions in the bureaucracies of church and state.

Students (male, not female) entered the university around the age of 14 already with a basic knowledge of Latin, the language of scholars and clerics across all of Western Europe. Ideally the student would first obtain the bachelor's degree in the Arts faculty, where he studied primarily the arts of language, logic, and natural philosophy or science, all based loosely on the Late Roman trivium (Latin grammar, rhetoric, and logic) and the quadrivium (mathematics, geometry, astronomy, and music). Many students could not afford to obtain higher degrees, and some left even before obtaining the Bachelor of Arts degree. Nevertheless, what education they gained was of great use to them in improving their lot socially and economically. If the student had economic support, he would obtain the degree of Master of Arts (from the Latin *magister*, or teacher, interchangeable with "doctor," which

➤ THE STATUTES OF POPE GREGORY IX FOR THE UNIVERSITY OF PARIS, 1231

"Gregory, the bishop . . . to his beloved sons, all the masters and students of Paris—greeting and apostolic benediction. . . . [C]oncerning the condition of the students and schools, . . . each chancellor [of the cathedral of Notre Dame], . . . at the time of his installation . . . shall swear that, in good faith, according to his conscience, he will not receive as professors of theology and canon law any but suitable men. . . . Before licensing anyone, . . . the chancellor shall make diligent inquiries . . . concerning the life, knowledge, capacity, purpose, prospects and other qualities needful in such persons; and after the inquiries . . . he shall grant or deny the license to the candidate, as shall seem fitting and expedient. . . .

In other matters, . . . we grant you [the masters] the right of making constitutions and ordinances regulating the manner and time of lectures and disputations, the costume to be worn, the burial of the dead; and also, concerning the bachelors, who are to lecture and [at] what hours, and on what they are to lecture; and concerning the prices of the lodgings or . . . interdictions [prohibitions] of [any and all of] the same; and concerning fit punishment for those who violate your constitutions and ordinances, by exclusion from your society."

Gregory IX, "Statutes of Gregory IX for the University of Paris," in *Translations and Reprints from the Original Sources of European History*, Vol. 2, No. 3, edited and translated by D. C. Munro (Philadelphia: Department of History of the University of Pennsylvania, 1902), 7–9.

also means teacher). Many ended their schooling at this stage. Those with patronage and/or benefices (income from an ecclesiastical office) might proceed to one of the four higher faculties: theology, canon (or church) law, Roman (or secular) law, and medicine. The successful student would receive another bachelor's degree, then the master's degree. Once a student incepted, or was accepted, as a master in any faculty, he was required to teach for two years, a period known as

a regency, or reign. Many Masters of Arts seeking higher degrees took classes in one of the higher faculties while serving their regency in Arts. As masters, they were granted the license to teach anywhere, although in practice recognition of the license was not automatic from institution to institution.

Courses were taught by lecture, either ordinary (taught by masters) or extraordinary (or cursory, taught by formed, or graduated, bachelors), and consisted of reading and commenting on the assigned text. The method included the use of the *quaestio*, or scholastic method, which entailed posing a question, listing the authorities for and against, and then resolving the problem and responding to the objections. Examinations were in the form of oral disputations, or determinations, held at certain specific times, such as Lent. Masters were also required to hold public disputations in which they debated anyone on anything. Although licensed to teach, the masters did not form a permanent teaching class. Most, after their final two-year regency, left the university to find gainful employment.

Despite antecedent ancient and Islamic educational models, the medieval European university was a unique institution in terms of organization, methods of instruction, and privileges. Medieval European universities provided the foundation for modern universities throughout the world with respect to the types of degrees offered, the division of curriculum into lower and higher faculties, and the mission of preparing graduates for future employment.

The Study of Foreign Languages in European Universities

Although knowledge of Latin was essential to study at all European universities, the acquisition of other foreign languages did not initially play a significant role in the university curriculum. However, three factors served to increase interest in their study. First, many scholars began to recognize the importance of Arabic, Greek, and Hebrew for philosophical and scientific study. Second, the development of a strongly evangelical spirit, especially with the establishment of the mendicant orders (most notably the Franciscans and Dominicans), spurred interest in learning the most important non-Christian languages for missionary purposes. Finally, the humanist movement, with its emphasis on textual criticism and a growing interest in the original languages of the Bible and classical learning, encouraged the study of Greek and Hebrew at European universities.

The intellectual riches of the Muslim world had already begun to attract Western interest by the tenth century CE. Already in the 960s, Gerbert of Aurillac, the future Pope Sylvester II, traveled to Spain to study Arabic mathematics. He quickly established a reputation as the most learned man of his day (leading some to speculate that he had made a bargain with the Devil). In the decades that followed, Christian scholars continued to seek access to Islamic learning, both in Spain and Sicily. At the same time, an increasing number of translations of Arabic, Greek, and Hebrew texts flowed in the opposite direction.

By the time of the foundation of the first universities in the twelfth century, a significant

➤ **RAMON LLULL, A TREATISE ON THE STUDY OF EASTERN LANGUAGES (1298–1299)**

In 1298 or 1299, Ramon Llull sent a letter to the masters of the University of Paris in hope of persuading them to establish chairs of Eastern languages for missionary purposes. The following is an excerpt from that plea.

“Here the prick of conscience stings me and compels me to come to you, whose high discretion and wisdom it behooves to act in such a matter, so pious, so meritorious, in a service so grateful to God and useful to the entire world, namely, that here at Paris, where the fountain of divine wisdom rises, where the light of truth shines on Christian peoples, there should be founded study of Arabic, Tartar [Mongol], and Greek, that we, having learned the languages of the adversaries of God and ourselves, by preaching to and teaching them may overcome their errors in the sword of truth and render the people acceptable unto God and convert enemies into friends. If this be done and it please God that it so be, Christen-

dom will receive the greatest exaltation and extension. And of this so inestimable thing you will be the foundation, and thou, university of Paris, wilt by no means be least among the doctors, for from thee will come light to all peoples, and thou wilt offer testimony to the truth, and masters and disciples will flock to thee, and all shall hear all sciences from thee. What good will the Greeks and Arabs have in their volumes that will not be known to thee, when thou shalt understand their tongues without an interpreter? Who will estimate how great praise, how great honor to God, how great compassion of charity towards poor sinners, and how great good would result in and from this place?”

—David Scheffler

Lynn Thorndike, ed. and trans., *University Records and Life* (New York: Columbia University Press, 1944), 127.

body of Greek and Arabic texts had been translated into Latin, and by the thirteenth century nearly the entire extant corpus of Aristotle had been translated. At the same time, an increasing number of university scholars were proficient enough in Greek and even Arabic to consult these texts directly. At Oxford, two of the most famous scholars of the day, Robert Grosseteste (d. 1253) and Roger Bacon (d. 1294), were especially interested in foreign languages. Grosseteste organized the first translation of Aristotle's *Nicomachean Ethics*, and Roger Bacon studied Greek, Hebrew, and Arabic. Their language skills, however, were obtained outside of the official university curriculum, which had as yet not institutionalized their study.

Formal efforts to introduce the study of languages into the curriculum of the schools received additional impetus with the foundation of the mendicant orders and their arrival at the universities in the mid-thirteenth century. The mendicants were first and foremost preaching orders. As such they enthusiastically supported training in foreign languages.

In 1236 the chapter general of the Dominicans required the establishment of schools for the study of foreign languages within every province of the order. In 1256 the master general of the Dominican Order, Humbert of Romans, commended the brothers for their study of “foreign tongues to spread the name of our Lord Jesus.” Inspired by the same evangelical spirit, the Franciscan tertiary, Ramon Llull, founded a school in his native Majorca that focused on the study of Eastern languages, most notably Arabic and Aramaic (Chaldean).

In 1312 due in large part to the efforts of Ramon Llull, the council of Vienne ordered the establishment of two teachers of Hebrew, Arabic, and Aramaic at the universities of Paris, Oxford, Bologna, and Salamanca and at the papal court. Although Greek was taught in Florence in the 1360s and some traces remained of the study of Hebrew at Oxford in the 1320s, the decree was not generally followed. As a result, those who wanted to study foreign languages continued to rely on schools outside of official university structures until the mid-fifteenth century.

Driven in part by the growing importance of the humanist movement, chairs in the study of Greek and Hebrew began to appear at many universities by the end of the fourteenth century. In 1397 the humanist Coluccio Salutati recruited Chrysoloras, a Byzantine diplomat, to teach Greek at the University of Florence. His pupils quickly established the study of Greek in many northern Italian universities. There is also some evidence of the study of Greek, Hebrew, and Aramaic at Paris in the 1430s as well as at many of the newly founded German universities.

Although the study of foreign languages never held a dominant position in the medieval universities, by the end of the fifteenth century religious, political, and intellectual leaders increasingly saw the study of languages, especially Greek and Hebrew, as essential to the mission of the university.

Literary Neoclassicism among Europe's Humanist Scholars

Although medieval European intellectual traditions included classical authors, humanist writers, scholars, and teachers began to look at these works in new ways. Unlike the scholastic tradition, which applied dialectic, or logic, to the vast body of medieval commentaries and often relied on *florilegia* (excerpted portions of a text), humanists placed greater emphasis on the texts themselves. In addition, they increasingly applied the skills of textual criticism to the inherited body of classical texts while gathering and

emending ancient works that had been lost or little used during the Middle Ages.

By the late thirteenth and early fourteenth centuries, protohumanists such as the notary Lovato dei Lovati (1240–1309) and his talented pupil and fellow Paduan Albertino Mussato (1261–1329) combined the desire to compose classical-style poetry with the application of increasingly sophisticated philological tools to ancient texts. Lovato focused on the tragedies of Seneca, which he himself had rediscovered, while Mussato composed a Senecan drama to warn his compatriots of the dangers of tyranny.

The next generation of humanists applied neoclassical styles to a variety of literary forms. Geri d'Arezzo (1270–1339) composed classical-style letters. Dante Alighieri (1265–1321) wrote Vergilian bucolic poetry. Petrarch (1304–1374) wrote letters in the style of Cicero. Coluccio Salutati (1331–1406) wrote a neoclassical treatise on tyranny derived from Lucan. Leonardo Bruni (1370–1444) wrote a classically inspired oration in praise of the Florentine Republic. By the end of the fifteenth century, humanist influence was evident in the universities of Spain, most noticeably Salamanca, in England, and within many German-speaking lands.

As humanist influence expanded geographically, humanist scholars extended their interests beyond the emulation of classical styles. Lorenzo Valla (d. 1457) applied his knowledge of philology to establish conclusively that the *Donation of Constantine* was a forgery. In their efforts to track down ancient texts, humanists edited and published a large body of medieval works, most famously those of the tenth-century playwright Hrotsvitha of Gandersheim, which the German arch-humanist and first imperial poet laureate Conrad Celtes (1459–1508) rediscovered in the late fifteenth century. Finally, some hu-

Painting of Dante Alighieri by Renaissance painter Giotto di Bondone. (Corel)

▶ LEONARDO BRUNI, *ON THE STUDY OF LITERATURE*

Around 1424, Leonardo Bruni presented to Battista Malatesta, a renowned female scholar, an essay on the study of literature, from which this excerpt is taken.

“In sum, then, the excellence of which I speak comes only from a wide and various knowledge. It is necessary to read and comprehend a great deal, and to bestow great pains on the philosophers, the poets, the orators and historians and all the other writers for thus comes that full and sufficient knowledge we need to appear eloquent, well rounded, refined and widely cultivated. Needed is a well developed and respectable literary skill of our own. For the two together reinforce each other and are mutually beneficial. Literary skill without knowledge is useless and sterile; and knowledge, however extensive, fades into the shadows without the glorious lamp of literature. . . . It was the two joined together that advanced the glory and fame of those ancients whose memory we venerate; Plato, Democritus, Aristotle, Theophrastus, Varro, Cicero, Seneca, Augustine, Jerome, Lactantius, with all of whom

we can scarce decide whether it is their knowledge or their literary power that is the greater.

To conclude: the intellect that aspires to the best, I maintain, must be in this way doubly educated, and it is for the sake of acquiring these two knowledges that we mass up our reading; yet we must also take stock of the time at our disposal. . . . It is religion and moral philosophy that ought to be our particular studies, I think, and the rest studied in relation to them as their hand-maids, in proportion as they aid or illustrate their meaning; and it is with this in mind that we must fix upon the poets, orators, and other writers; in literary study care should be taken to employ noble precepts and long and perceptive observation, and never to read any but the best and most approved books.”

—David Scheffler

Source

Craig W. Kallendorf, ed., *Humanist Educational Treatises* (Cambridge, MA, and London: Harvard University Press, 2002), 123.

manists, most notably Erasmus of Rotterdam (1467–1536), also began to apply their skills to patristic and biblical texts, leading to new translations of the Bible from the original languages.

Humanist influence on vernacular literature was also profound. Although many early humanists expressed disdain for the vulgar tongue, the fact that the much-admired authors Petrarch and Giovanni Boccaccio (1313–1375) wrote in both Latin and Italian ensured a place for the vernacular in humanist circles. Baldassare Castiglione’s (1478–1529) influential work *The Courtier* reflected the influence of Neoplatonism, while the poetry of Ludovico Ariosto (1474–1533) and Torquato Tasso (1544–1595) consciously drew upon Vergilian forms for their vernacular poems. Beyond Italy, humanist influence on the vernacular is evident in the writings of François Rabelais (1483–1553), Edmund Spenser (1552–1599), and to a lesser extent Miguel de Cervantes Saavedra (1547–1616), to name only a few.

Despite the growing influence of the humanists, the emphasis on philology, the study of classical authors, and their classicizing styles were not without critics. Some questioned the usefulness (or worse) of pagan letters to a Christian society. Others bristled at the suggestion that the entire apparatus of scholastic debates had been based on inadequate editions of ancient texts. As humanist approaches began to influence the higher studies (medicine, law, and especially theology), the criticism grew even more pronounced. Professors of theology, law, and medicine resented the presumptive attitudes of humanist scholars. They were, according to the established professors in these fields, unqualified (most were only trained in the liberal arts), uninformed, and frequently unorthodox. Even an author with humanist leanings such as Boccaccio continued to question the compatibility of Christianity and the pagan authors.

Humanist Academies and Traditional Universities—The Struggle for Intellectuals in Western Europe

Beginning around the mid-fourteenth century, distinctions between educational programs in northern and southern Europe began to appear as Renaissance educators in Italy emphasized the *studia humanitatis* (humanistic studies), or the cycle of disciplines consisting of grammar, rhetoric, poetry, history, and moral philosophy. Although Renaissance educators often referred to this suite of disciplines as the liberal arts, they actually differed in significant ways from the liberal arts curriculum that was taught in medieval universities. The universities taught a set of disciplines inherited from late antiquity called the trivium, consisting of grammar, rhetoric, and dialectic (or logic), and the quadrivium, composed of arithmetic, geometry, astronomy, and music. Of these seven liberal arts, dialectic or logical analysis was preeminent in all respects, especially from the late twelfth century onward. Differences between curricula set apart the Italian Renaissance humanists (that is, teachers of the *studia humanitatis*), who stressed studying the compositional art and thought of writers from antiquity, from their medieval counterparts of the universities, who followed a method of analysis and expression often called scholasticism.

Universities, such as the one in Paris, taught the trivium, which focused on the study of word usage, argument, and language, and the quadrivium, which focused on mathematics, and the higher, more advanced disciplines of theology, civil and canon (church) law, and medicine using the methods of scholasticism. The essence of the scholastic method was arranging questions or issues in logical order and then approaching each question didactically, positing the (often conflicting) views of authorities and concluding with an opinion or a resolution of conflicting authorities.

The *studia humanitatis* taught in Renaissance academies, such as in Florence, stressed a curriculum that focused on language, literature, and moral philosophy and rejected what the humanists thought of as the rigid and narrowly technical educational program of the universities. The humanists' curriculum reflected the Renaissance enthusiasm for antiquity, especially early Christian and ancient Latin and Greek authors. Humanists believed that ancient authors bridged the centuries and that they held universal significance, which spoke more meaningfully to students than did the scholastic programs of the universities. In fact, humanists consciously juxtaposed the *studia humanitatis* to scholasticism of the late medieval universities and attacked it on several fronts. First, the universities taught students to write in awkward, ineloquent Latin that humanists labeled "barbaric" when compared to the eloquent Latin taught in their academies in imitation of ancient authors, such as Cicero. Second, the content, which focused on practical training for administrative careers in the Church or royal government, was irrelevant and did not adequately address the moral questions facing the leading citizens of the self-governing Italian city-states. According to the humanists, the classical authors addressed the abiding questions that were central to the human condition, such as how to live a moral and virtuous life, how to arrive at self-understanding, or how to govern effectively.

Humanistic education fit the needs of the Italian urban elite, who saw themselves as active participants in the civic life of their city-states. Renaissance academies received support from either civic governments or wealthy patrons. A

➤ VITTORINO DA FELTRE—HUMANIST EDUCATOR

In mid-1423 Vittorino (Rambaldoni) da Feltre (1378–1446) traveled from Venice, where he had run an independent boarding school for young boys, to Mantua at the invitation of Marquis Gianfrancesco Gonzaga. There Vittorino established a school called the Casa Giocosa (House of Joy) for the Gonzaga and other children of the court that he presided over for the rest of his life. Vittorino's school became famous as a boarding school for the children of wealthy elites, but he also took in many poor students, whom he boarded at his own expense. His students ranged in age from 4 to 20 years, although most entered his school between age 12 and 14, and they usually remained for 4 to 6 years. Although most of his students were boys, at least three students were

girls, including two Gonzaga daughters. Vittorino believed in a strong academic and athletic program, and he thought that students learned best when they lived and studied in close proximity to their masters (or teachers).

The Casa Giocosa became one of the foremost schools in Italy. Vittorino taught future princes, humanists, and masters. Schooled in the *studia humanitatis*, with an emphasis on oration, poetry, and history, Vittorino's students helped to spread humanistic education, since when they assumed positions of authority as adults they established or sought out humanistic schools for their own children.

—Jan K. Bulman

number of humanists wrote on the importance of humanistic education and the best way to teach students and created model schools based on these principles. Pier Paolo Vergerio (ca.1368–1444) wrote on the importance of educating leaders, and Vittorino da Feltre (1378–1446) made his ideas a reality when he established a school for the children of Gianfrancesco Gonzaga of Mantua. Guarino Guarini da Verona (1434–1513) directed a school similar to Vittorino's for the children of Duke Niccolò III d'Este of Ferrara and others.

The *studia humanitatis* launched a shift in the educational curricula that had profound effects throughout Europe, and by about 1500 this humanistic curriculum had spread to France, Germany, the Low Countries, and England, altering educational programs north of the Alps as it had in Renaissance Italy.

The Mexica *Telpochcalli* and *Calmecac*—Secular and Religious Education for Boys

The Mexica *telpochcalli* and *calmecac* were schools intended for common and noble boys, respectively, and both prepared young men for their future careers and their place in a structured society. The *telpochcalli* was intended to prepare youths for secular careers, whereas the *calmecac* trained future religious and high political leaders. Each type of school used brutal discipline and rituals to impress on the students that they must follow society's norms, thereby helping to ensure that the existing order was accepted and sustained.

The *telpochcalli*, translated as “Youths’ Houses” or “Bachelors’ Houses,” were associated with the different wards, or neighborhoods, in Tenochtitlan and other Mexica cities. Each ward

► THE CODEx MENDOZA

This page from the Codex Mendoza shows 15-year-old boys going to the *calmecac* and the *telpochcalli* for training.

The Codex Mendoza, apparently commissioned by Antonio de Mendoza, viceroy of New Spain, and shipped to Europe in 1542, was created to illustrate the history and culture of the Mexica for Charles V using native art styles and motifs. French pirates captured the galleon carrying the codex and sent it to France, where it was acquired by Andre Thevet, cosmographer to the French court. Richard Hakluyt later purchased the codex and brought it to England. The last owner was John Selden, whose heirs deposited the codex at the Bodleian Library at Oxford University in 1659.

This illustration comes from a section of the codex that outlines everyday life among the Mexica. The top half shows how young men around age 15 received religious training at the *calmecac* and training in secular matters at the *telpochcalli*. Each student wears distinguishing clothing and has a haircut associated with his career. Each was also marked with ritual scars on his head and chest. The 15 round dots below the boys indicate the age of the students. The text is Spanish, describing how one boy is being delivered by his father to the *calmecac* to be trained as a priest while the other is being sent to the *telpochcalli* to learn the duties of a Mexica man.

The lower portion shows two young people getting married. At the bottom of the illustration, the matchmaker who arranged the marriage is carrying the bride to the groom's house on her wedding night. Four women precede them with torches to light the way. The upper part of the illustration shows the wedding ceremony. The couple's clothing is knotted together, signifying the joining of their lives. Four elders surround them to

(The Art Archive/Bodleian Library Oxford)

offer advice and witness the marriage. Between the couple is a fire with copal incense, to be offered to the fire god. A feast was held in the couple's honor, and the other symbols signify the different kinds of food, tobacco, and flowers offered to the guests. Special importance is given to the pulque, an alcoholic beverage served on special occasions.

—Timothy J. Watts

had its own *telpochcalli*, and much of the ward's public business took place there. Boys were dedicated to the *telpochcalli* as infants but began to attend when they were nine years old. They spent their days at the *telpochcalli*, returning home to sleep at their parents' homes. Each morning the appointed master organized them into groups to undertake public works, with the tasks ranging from building houses to tending

fields owned by local temples. After working all day the boys returned to the *telpochcalli*, where they learned the rituals and activities that all adult Mexica men were expected to know and follow.

Slightly older boys at the *telpochcalli* were trained to use weapons, and at puberty they accompanied soldiers into battle. By the time they were 15 years old, they were fighting alongside

the soldiers. They also manned guard stations in the neighborhoods to keep order.

Discipline in the *telpochcalli* was strict, and virtues such as obedience, honesty, and cleanliness were expected. Minor violations of the rules were brutally punished with bloodletting and beatings. More serious violations, such as drunkenness, brought immediate death.

Boys remained at the *telpochcalli* until age 20. Their parents could then petition for their release to marry a woman the parents had chosen and set up their own households.

In contrast, attendance at the *calmecac* was restricted to the nobility. Only seven were recorded as existing in Tenochtitlan. Each *calmecac* had a priest, known as the Mexicatl teohuatzin, in overall charge. Another priest known as the Tepan teohuatzin oversaw the boys.

After being dedicated to a *calmecac* as infants, boys formally joined the school at age 15, although some began as early as 5 or 7 years of age. They went through a series of ranks and performed increasingly important jobs. The value of traditional virtues was also impressed upon them with brutal punishments. Bloodletting was commonly used both as a punishment and a sacrificial ritual, along with more severe punishments. While most students were trained as warriors, they also received education in painting, interpreting and using calendars, astronomy, and reading sacred books. Philosophical questions, such as the importance of gods in human life, were also studied. Ultimately, students at the *calmecac* became the guardians of Mexica culture and religion. Those who became priests became the intermediaries between humanity and the gods, and it was believed that their care in performing rituals ensured good weather and protection for the people. Other graduates of *calmecacs* were the military leaders of Mexica armies, important government officials, and emperors.

Mexica Convent Schools for Noble Girls

Education was highly regarded by the Mexica, who saw it as a key to helping children become productive persons who knew their role in society and could help promote the common good. For most women, their role was centered in the home, where they were charged with maintaining order, feeding their family, and producing children who fit well into society. Some noble women, however, were given the opportunity to be educated in schools associated with temples, becoming priestesses who served an important role of intermediary between certain gods and people.

When a girl was 20 days old, her parents would begin the process of deciding the direction of her life. Nearly all children, including commoner girls, attended the *telpochcalli*, or neighborhood school. Mexica society was quite unusual during the fifteenth and sixteenth centuries in offering basic education for all children, including females. Some noble girls, however, would be dedicated by their parents to attend one of the *calmecac* schools that were associated with important temples in Tenochtitlan. These infant girls received small incisions on their hips and breasts to mark their dedication to the gods.

Infants were also presented with miniature symbols of the duties expected of them as adults, and girls received tiny brooms, baskets, and distaffs and spindles, since they would be responsible for the home. Bernardino de Sahagun's work on Aztec history and culture indicates that even children intended for the *calmecac* received the gifts usually given to their gender, since they were also expected to possess skills to fulfill their duties. Being a productive member of society was a religious as well as a secular duty. When a girl reached the age of four years old, her parents began to train her in the basic duties expected of all Mexica women. These tasks included

> FERNANDO ALVA IXTLILXOCHITL

Fernando de Alva Cortes Ixtlilxochitl (d. 1648), a Mestizo, or person of mixed Spanish and Mexica blood, was a direct descendant of Ixtlilxochitl I and Ixtlilxochitl II, rulers of the state of Texcoco, and was also the great-great-grandson of Cuiclahuac, the next-to-the-last Aztec ruler of Tenochtitlan. Fernando Ixtlilxochitl's father and maternal grandfather were both Spanish. He was educated at the Imperial College of Santa Cruz de Tlatelolco, where he studied both Spanish literature and Nahuatl.

Although Ixtlilxochitl came from an illustrious family, he lived most of his life in poverty. He wrote a number of histories of the pre-Spanish Mexica, and he is one of the most important sources on Aztec society and beliefs. Unlike most other Spanish writers, Ixtlilxochitl used Mexica writings and oral traditions as source materials. His earliest works were four *Relaciones* that tell the story of Mesoamerican society from the perceived beginning of the world to the fall of the Toltec capital at

Tollan. Much of the information and most of the rulers listed therein are not found in other works. Ixtlilxochitl has been criticized because some information is repetitious and the chronology is confused.

Ixtlilxochitl's most important work is the *Historia de la nacion Chichimeca*. Most of the history tells the story of the rise of the Triple Alliance of Tetzcoco, Tenochtitlan, and Tlacopan, which became the Aztec empire. Ixtlilxochitl assigns most of the credit and glory for the empire that the alliance created to his ancestors from Texcoco. As such, Ixtlilxochitl provides an interpretation different from the one found in most Spanish writings. His work is also valuable for its insights into Mexica culture and society and for its highly organized and sophisticated nature. In his histories, Ixtlilxochitl recorded information about the formal and informal roles that Mexica noble women played and the training they received.

—Timothy J. Watts

weaving, cleaning, and cooking and were intended to produce a person who would accept the established order of society. Around the age of 12, girls would attend the *telpochcalli*, although they were instructed separately from the boys. Girls learned religious songs and dances along with Mexica history and traditions. After classes at the *telpochcalli* concluded, the girls and boys would be taken to the *cuicacalli*, the House of Song, where they learned religious songs and dances. The *cuicacalli* was associated only with the *telpochcalli*. Girls continued to attend the *cuicacalli* from the age of 12 until they were married.

Girls from noble families could attend the *calmecac* when they were 15 years of age. The curriculum was more intellectually challenging than that of the *telpochcalli*, and girls learned to read, write, and draw. They also received training in astronomy and the timing for religious rituals. Separate facilities were maintained for boys and girls. Students swore an oath to remain celibate, and sexual misconduct was severely punished, with penalties ranging up to death. Mexica children were also taught that premarital sex

was offensive to the gods and would result in deformities and failure to mature. Noble families taught their children that sexual relations outside of marriage displayed a lack of self-discipline common to the lower classes.

The woman who mastered her studies became a *cibuatlamacazqui*, or female priest. Although the most important religious ceremonies were performed by male priests, the priestesses were essential for some rituals, especially those related to fertility. The feast of Ochpaniztli was dedicated to the mother goddess Toci, and the rituals were celebrated by priestesses. Other priestesses had the responsibility to ritually clean and decorate the temples. In all ceremonies celebrated by the priestesses, they were carefully dressed to demonstrate the importance and solemnity of the ritual. In a ceremony known as Quecholli, priestesses dressed to represent goddesses carried ears of corn in a procession through Tenochtitlan. At sundown, they threw colored maize kernels and pumpkin seeds to the crowds as symbols of a good harvest to come.

Priestesses could leave the priesthood to get married. A suitor had to ask her family, the lead-

ing priestess of the temple, and the woman herself to gain permission. Only when everyone approved could such a priestess leave her religious duties to be married and lead the life that most Mexica women accepted. Those priestesses who did not get married continued to care for the temples and instructed the girls in the convent schools.

The Yacha Huaci, Schools for the Children of Inca Nobles

To maintain their extensive empire, the Inca needed a class of noble warriors who were familiar with the traditions, religion, and accomplishments of those who had gone before. The Yacha Huaci, or House of Learning, was an imperially sponsored school in Cuzco, the Incan capital city, where noble male youths were given the training they needed to maintain the empire in accordance with its strict hierarchical structure.

The founder of the Yacha Huaci was the sixth emperor Inca Roca (r. ca. 1350–ca. 1380), who built a school for the sons of Cuzco's nobility. The ninth emperor, Inca Pachacutec (r. 1438–1471), enlarged the Yacha Huaci, creating a complex of buildings joined by a common facade in the center of Cuzco. Moreover, because

► THE YACHA HUACI, SCHOOLS FOR THE CHILDREN OF INCA NOBLES—QUIPUS

Quipus (khipus) were used by the Incas to record numerical and other information using a decimal system. The position of a thread and the number and form of knots on a thread have numerical values. The Spanish colonial authorities recognized this fact and at first accepted Incan quipus to settle legal disputes regarding payment and similar financial matters.

The Spanish acceptance of quipus soon changed when they realized that the strings could well represent other information. Different-colored threads and spacing as well as different kinds of knots could be used as mnemonic devices to carry messages. Many conquistadores also considered the quipus to be related to pre-Columbian religious beliefs. Most quipus were destroyed, and today only about 600 remain in existence.

Without knowing the context in which individual quipus were created, deciphering them is nearly impossible. Some archeologists believe, however, that they represent a three-dimensional form of written language, using a binary code. Those Incans who were trained to read the code could spread the message to their listeners, similar to the way in which a musician uses a score to play a song.

—Timothy J. Watts

A quipu, the knotted cord device used by the Incas for keeping accounts, Peru, 1430–1532. (Werner Forman/Corbis)

the empire expanded greatly during his reign, Pachacutec included noble sons from the various provinces into the Yacha Huaci's student body.

Unlike the Aztec *calmecac*, the Yacha Huaci had a more informal curriculum, with emphasis on practical education. Primary attention was given to teaching fluency in the Quechuan language, which was used throughout the empire. Oratorical skill was highly valued in Incan society, and correct and elegant speech was considered a mark of authority among the nobility. Other important areas of instruction included the empire's legal system and Incan religious beliefs and cults.

Most of the students' time, however, was taken up with learning Incan history and legends. Teachers used short standardized poetic verses to teach students about the exploits of earlier rulers and great soldiers and about the different clans that made up the nobility and their relation to the emperor. Such schooling in culture and tradition depended upon students learning extensive amounts of oral poetry. To memorize the material, students learned how to use *quipus*, or multicolored sets of knotted threads. Although archeologists remain uncertain about how information was recorded on the quipus, they do know that different types of knots on different types and colors of threads had specific meanings. The teachers in the Yacha Huaci were known as *amautas*, or sages, a title that reflects the fact that they were highly regarded for their

learning and wisdom. There may have been as few as four or five *amautas* at one time teaching in the Yacha Huaci, aided by poets and other scholars. When students had completed the curriculum, the *amautas* tested their knowledge in a series of oral exams. After successfully passing the exams, students completed their training at the emperor's court. Under the mentorship of a particular noble, they learned court etiquette, administration, and construction of public works such as roads or water systems.

Some writers have characterized the Yacha Huaci as a form of university, although it seems to be a questionable use of the term "university." Leaving aside semantic quibbling, it suffices to note that the Yacha Huaci's most important role was to transmit Incan traditions and culture, and in doing that it helped stabilize society and maintain the existing system of beliefs.

■ Introduction: Art and Architecture—The Monumental Balanced by the Human-Sized

Whereas states and highly organized religions (and often they were indistinguishable from one another) built monumental structures that served their needs, such as effigies of rulers, palace complexes, temples, mosques, and churches, the persons ruling over these entities were also served by artists and artisans who crafted smaller human-sized items of beauty and utility in the service of their masters. Moreover, these rulers also constructed

edifices in the service of those whom they governed, such as hospitals, caravansaries, and marketplaces. Beyond this, artists and artisans also served directly the ever-growing and insistent demands of "commoners" for their own items of beauty and utility. This was true at least for those common folk who resided in towns and cities and enjoyed at least a modicum of disposable income. Indeed, more often than not the useful was crafted with an eye to beauty, such as the

fine ceramic wares of China and the Islamic world, the hand scrolls of China and Japan, the books of the Islamic and Christian worlds, the feather and textile blankets of the Americas, and the ceremonial clothes of rulers, priests, and other great officials around the world. These and numerous other items of this sort made life comfortable and delighted the eye. More than that, they usually, as the phrase goes, made a statement, a statement of the status and wealth (and even power) of the individual who possessed and displayed them.

Away from the cities in Central Asia, parts of East Asia, sub-Saharan Africa, the Americas, and Oceania, pastoral, agricultural, and hunter-gatherer cultures expressed themselves spiritually and artistically in carved rock art as well as in the fashioning of beautiful items of everyday use, including weapons. Indeed, the crafting of handsome as well as deadly weapons was raised to a high art in a number of both settled and nomadic cultures, such as the steel swords of Afro-Eurasia, crafted with loving care from Spain to Japan, and the compound recurved bows of the steppe.

Another phenomenon at work during this half millennium was the transit of artistic styles and motifs across Afro-Eurasia and the Americas. One example among many was the manner in which ceramic artisans in Persia and Iraq continued to emulate the *sancai* (three-colored) glazes of Tang China's export wares well into the twelfth and thirteenth centuries.

Perhaps most striking to the casual tourist are the great edifices raised during these five centuries: the Romanesque and Gothic cathedrals of Western Europe; the temples erected to the worship of Shiva and Vishnu by the Chola monarchs of South India; the temples of Angkor Wat; Byzantine-style churches raised in Russia, Serbia, and other areas of Eastern Europe and the Balkans; the temples of Mesoamerica; the stonework structures of the Incas; and the great palace complex in Beijing known as the Forbidden City. All are symbols not only of great pride, wealth, and power but also of a highly developed aesthetic.

Finally, let us not forget art for art's sake: paintings, calligraphic scrolls, and countless other portable items of beauty that were created for the sheer love of beauty. Of course, more often

than not they were created with an eye toward profit and the satisfaction of a patron, but the purpose was still primarily aesthetic.

Every age creates its own forms of beauty in multiple ways, and this was no less true for all of human cultures around the world during this era. The entries that appear below can provide only a small sample of the richly variegated ways in which beauty was crafted in all sizes, at all levels, in so many different media, and around the globe from 1000 to 1500 CE.

—*Alfred J. Andrea*

The Artists of Sub-Saharan Africa

Art and artists flourished in sub-Saharan Africa between 1000 and 1500 CE, a period in which patronage and possibilities supplied by long-distance trade encouraged the growth in artistic production. Much of the visual art was associated with divine kingship, ritual, and political culture. Achievements in architecture, terra-cotta sculpture, copper-alloy casting, and ivory carving characterized the role of the arts in maintaining cultural memory systems across the continent.

Christianity's inroads in the Nile Valley and Ethiopian highlands earlier in the first millennium were grafted on an ancient urban world with extensive gold, silver, and bronze working skills; monumental stonework; and wide trade connections. Despite Islamic incursions after the seventh century, the Christian Church of Ethiopia survived around remarkable examples of stone architecture that required the mobilization of labor and resources by local elites. The thirteenth-century rock-hewn church of St. George at Lalibela was constructed within its deep quarry by carving the structure's interior and exterior out of one stone block more than 34 feet (10 meters) high. A proliferation of neck and handheld crosses fashioned of silver and brass and local illuminated manuscripts also mark the era's artistic and religious expression.

About the same time as Lalibela, the large southern African urban center of Great Zimbabwe also excelled in stone working, including entirely indigenous architectural and sculptural traditions. The site itself was partly built on a hillside, where impressive buildings, towers, and protective walls have survived the centuries.

► IFE—ARTS FROM THE CENTER OF THE WORLD

Ife's spiritual primacy is reflected in the urban growth and artistry of the royal capital. The Yoruba city of Ife (in present-day Nigeria) is claimed by oral traditions to have been the place where the gods descended from the sky to create the world. By at least the thirteenth century, the city housed royal artisans, who worked in clay, copper, glass, and ivory. Their terra-cotta, copper, and copper-alloy sculptures attained an astonishingly naturalistic style and may have figured in key rituals that sustained the connections between divine rulers and the spirit world.

The urban origins of Ife can be traced archaeologically to at least the fourth century BCE, and by 800 CE Ife had become an influential political and religious center. Yoruba rulers trace their lineage back to the creation of humankind out of clay at Ife. Whereas Yoruba women worked in clay, metalurgy was the exclusive domain of male artistry. Human figures are best known, but depictions of animals, diseases, and other subjects make the art a rich source for the historian. The arts of Ife challenged Western ideas about African art and fueled debates about the independence and antiquity of West African artistry.

—Candice Goucher

These labyrinths of stone were more than 30 feet (9 meters) high and were likely constructed by the ancestors of the region's Shona people without the use of mortar. It is also likely that the stone architecture marked important ceremonial and political features in the urban landscape that supported an estimated population of more than 10,000 through extensive trade with the Indian Ocean world in gold, ivory, and other goods.

Long-distance trade in metals provided resources for the royal arts of West Africa. At the political centers of Ife and Benin, lost-wax casting of copper alloys and sophisticated ivory carving techniques provided objects that legitimized political rule. Artisans were housed in palaces and patronized by the royal family. Control over trade in ivory and metals ensured a royal monopoly on artistic production. Portraits of rulers played a role in commemorative shrines

and rituals associated with divine kingship. Objects such as hip masks and medallions were likely used as more portable symbols of political authority outside the royal centers.

Islamic merchants played a role in enhancing West African trade and sometimes altered the organization and styles of the region's material cultures. Cotton-weaving technology spread along the trans-Saharan trade routes, and the horizontal loom of the Islamic world shifted textile-manufacturing industries into the hands of men. Religious prohibitions on human imagery gave way to the emphasis on rich geometric patterns in architectural decor, textiles, leatherwork, and Arabic-inscribed metal vessels.

Objects and artisans moved along the trade networks, and their artistry served as inspiration across vast distances. Leatherwork known in twelfth-century European markets as Moroccan actually originated in the region of what today is northern Nigeria. North African Islamic brass containers became items of prestige among the Akan elite in communities of southern Ghana. Although much of the art of African daily life did not survive the centuries, historical descriptions of hairstyles, basketry, textiles, wood and raffia masks, dance, and music suggest the rich interplay of visual and performing arts.

Artistic Interchange between China and Islam

Muslim traders formed communities in China as early as the seventh century during the height of the Tang dynasty (618–907), from where they

exported exotic items, largely over land, to Persia, Arabia, Syria, and other regions of the far-flung Islamic world as well as to the Christian and pagan lands to Islam's west and north. In return, caravans carried metalware, glassware, wine, and similar commodities to China. However, during the Song dynasty (960–1279), sea trade between China and the lands of the Indian Ocean grew dramatically in volume, thereby making the sea routes China's main avenue to the West and Islam's main thoroughfare to the Far East. The result was commerce that was safer, faster, and far larger in scale than ever before. As a consequence, the artistic interchange between China and Islam that occurred after the year 1000 had a profound impact on the development of Islamic art.

Of all China's exports, Song porcelains, noted for their pure whiteness, were especially appreciated by wealthy Muslim connoisseurs, and this ceramic ware became a major influence for the development of subsequent Islamic pottery. Demand for Chinese porcelain and ceramics was overwhelmingly high and could not be met solely by importation, but Middle Eastern Muslim potters lacked the raw materials in their native locales to produce exact replicas of these luxury wares. Most serious of all, their local clays could not withstand the high kiln temperature needed to produce true porcelain. This disadvantage encouraged innovation, such as Iranian potters' development of white slip (a thin clay overlay used for decoration) and the development in Iraq of an opaque white glaze. In this manner, Muslim potters were able to meet the demand for Chinese-style ceramics, and even if the quality was inferior, the price was right.

The Mongols eventually destroyed the Song dynasty, replacing it with their own Yuan dynasty (1279–1368) as part of an empire that stretched from the Pacific to the borders of Syria. Travelers and traders using the revitalized overland routes of the Silk Road enjoyed the protections and other advantages of the so-called Pax Mongolica, a period of relative stability and unity across Eurasia that lasted from around 1260 to about 1340. Although only severely limited numbers of such items have survived to our day, it seems that highly portable objects, such as Chinese woven silks, lacquerwares, and paint-

ings, made their way in large quantities along Eurasia's caravan routes to Iran and Iraq, the heartland of the Mongol Il-khanate of Persia (1256–1353), which became part of Dar al-Islam with the conversion of Il-khan Ghazan (r. 1295–1304). Here they served as the main sources of inspiration for Chinese-like designs that now appeared in Il-Khanid court art. Chinese motifs, such as flying cranes, ducks, phoenixes, and dragons, were now incorporated alongside classical Islamic decorations, such as complex designs of intertwined geometric and floral figures known as arabesque and inscriptions in Arabic or Persian.

In addition, Chinese painting began to play an important role in the development of Persian manuscript art. Coiled Chinese clouds, detailed landscapes, flowing plants, and Chinese flowers were adopted by Persian manuscript artists from the late thirteenth century onward.

Influences, however, ran both ways. As the scale of trade grew, Islamic tastes began to significantly influence wares produced in China. Densely decorated surfaces with geometric patterns were clearly adapted from Islamic ceramics, glass, and metalware, especially the exotic designs of Persian art. Moreover, the size of ceramic pieces produced by Chinese potters was influenced by the demands of the Islamic marketplace. Inasmuch as communal eating was a Muslim custom, export wares, particularly celadon ware (ceramics with a pale blue-green or olive-green glaze) and blue and white dishes, were produced at the appropriate large size for this market.

Like their Il-Khanid predecessors, the Turco-Mongol Timurids (ca. 1369–1506) were great patrons of art, and under their patronage Chinese porcelain continued its influence on Islamic ceramic production. Ming blue-and-white porcelain ware, produced with an underglazing of high-grade cobalt from Central Asia, was especially popular, with a significant amount of it imported by Timurid patrons as well as by patrons elsewhere in the Islamic world.

Timurid art went beyond merely imitating Chinese styles and motifs, whereby artists and artisans, under court patronage, used Chinese-inspired motifs as decoration for their own artistic expressions. Timurid chinoiserie (Chinese-

KITABKHANAS

Persian art matured during the Timurid Age, and it was royal and princely support more than anything else that made this possible. Patronage of the arts added to the Timurids' political and religious prestige, but most of the Timurids were also avid connoisseurs. More Persianized than their Il-Khanid predecessors, the Timurids accepted the Persian tradition that practicing the fine arts was an integral part of a prince's education. Consequently, some Timurid rulers and family members were accomplished artists, such as Baysunghur, a calligrapher (1397–1433).

Evidence strongly suggests that sometime in the 1430s the Timurids established royal workshops known as *Kitabkhanas* (literally book houses but more broadly understood as studios) in their leading centers of artistic activity: the Iranian cities of Tabriz and Shiraz as well as Herat, which today is located in Afghanistan. Housed in these *Kitabkhanas* were artists' materials and, most important, visual models—drawings and objects acquired largely from abroad through trade, diplomacy, and war. Thus inspired and supported, Timurid artists refined the Chinese-inspired motifs that characterized their work. One of the results of this institutional support was a standardization and idealization of motifs and compositions.

—Kumi S. Martin

inspired motifs that emphasized intricate patterns and elaborate decoration) flourished in every sort of artistic medium under the control of Timurid royal ateliers, or workshops. Of these media, the most notable were paintings, woodcarvings, manuscripts, textiles, bookbinding, and architectural decoration. Moreover, Timurid chinoiserie deeply influenced all subsequent Islamic art, such as that of Safavid Persia (1501–1736), Mughal India (1526–1858), and Ottoman Turkey (ca. 1302–1922).

The Visual Arts and Crafts of Dar al-Islam

The period from 1000 to 1500 was one of particular efflorescence in the Islamic world for arts and crafts, and they were as varied and as plentiful as were the many peoples, lands, and cultures that made up the Islamic Ecumene. Here we shall consider only a few of the more important and representative arts and crafts: ceramics, textiles, metalwork, and the architecture of mosques.

Ceramics

The production centers of Islamic ceramics were Iraq, Egypt, Syria, and Persia, and during this period potters achieved a series of extraordinary breakthroughs.

Around the tenth to the eleventh centuries, Islamic potters began to respond to the clear superiorities of Chinese ceramics to satisfy their local patrons. Despite lacking the clays of China that gave porcelain its unique translucence and whiteness, Islam's potters eventually were able to craft ceramics that rivalled the beauties of Chinese porcelain.

At the same time, Islamic potters produced types of glazed ceramics special to them. For example, lusterware, which is produced by adding metallic oxides to the glaze to produce a metallic sheen, became extremely popular. Initially the Mesopotamian area and Egypt were its primary centers of production, but following the fall of Egypt's Fatimid dynasty, Kashan in Iran became the Islamic world's finest center of ceramic production. In addition to dinnerware, other important products of Kashan were polychrome and luster tiles. Used to decorate buildings, they also served a religious function when

employed to define a mosque's *mibrab*, the niche in a wall that indicates the direction of Mecca and therefore the direction of prayer.

Under Seljuk rule, which basically controlled Anatolia, Iran, and Syria between about 1038 and 1194, Iran took the lead in ceramic innovation and production. As moneyed classes grew during this period, more sumptuous materials and time-consuming ceramic products were required to satisfy their tastes. A multicolored pottery known as *minai* (enamel), which required multiple firings at different temperatures, was invented in late-twelfth-century Iran. *Lajvardina*, a rare ceramic, was often decorated with cobalt blue, red, and white enamels and gold leaf and was often employed in the interior decoration of mosques and palaces. However, because of their cost and the intensive labor involved, production of both proved fleeting.

Textiles

Textiles were woven throughout the Islamic world and at all social levels, from nomadic households to royal studios. They also served many purposes, ranging from simple daily garments to luxurious ceremonial gowns and carpets that graced the floors of nomadic tents and royal courts. Likewise, they were made from a wide range of materials, especially cotton, linen, wool, and silk. Textile decorative motifs drew inspiration from a wide variety of sources. Pre-Islamic Sassanian art, Byzantine decoration, the artistic imagery of China, Central Asia, and Coptic Christian Egypt were only some of the sources from which Islamic weavers drew their inspiration. Even tapestries with Western heraldic and Christian iconographical decorations were woven for European Christian patrons, some of which are preserved today by churches and families in Europe. So valued were Islamic fabrics in the West that they were often used to wrap the holy relics of saints.

The Mamluk era in Egypt and Syria (1250–1517) was an important period in terms of Islamic class development during which an elaborate and rigid social system took shape. Along with it came an increased taste for luxuries, especially in clothing and other textile products

whose materials, colors, and designs were used to indicate the social and economic rank of the wearer or owner. Silk interlaced with gold or silver threads, for example, became a much-prized commodity.

The early history of Islamic carpet production is unclear, but clearly by the year 1000 it was a major industry that had centers of production that ranged from a few families in a village to state-owned factories. Indispensable as furniture for Muslim social life, carpets, made largely from wool, provide warmth and comfort for persons sitting or standing on a floor or the ground, riding a horse, or praying in a mosque, at home, or on the road. Most carpets were woven domestically for family use, but more luxurious carpets were produced in studios and factories for export as luxury items and diplomatic gifts as well as to beautify the homes and courts of the rich and powerful.

Metalwork

The Middle East has produced fine metal objects since antiquity, and the tradition was carried on with great skill throughout this vast region. In the twelfth century gold and silver metal ware with inlay became popular. Until then, the competition between metal and pottery did not often favor metal ware. Precious metals such as gold and silver were expensive, and lusterware, which has a metallic body, satisfied patrons' desires for glitter. The technique of inlay was not new to Islamic metal craftsmen, but serious shortages of precious materials seemed to encourage the revival of inlaid metal work, whereby a small amount of gold, silver, or copper was used as inlay decoration in a vessel made of baser metal. Khorasan province, especially the city of Herat (today in Afghanistan), was the center of inlay production, and Mosul in Iraq was not far behind. In this craft, surface decoration became extremely intricate. Hunting scenes, princely activities, and zoomorphic and astrological motifs were inlaid in a variety of objects, such as bowls, plates, ewers, incense burners, and candlesticks. The motifs were very similar to those depicted in contemporary textiles and manuscripts.

ISLAMIC FIGURATIVE ART

A common misperception is that Islamic art consists totally of nonfigurative decoration such as geometric patterns, abstract floral designs, and inscriptions. To the contrary, figurative representations were an integral part of Islamic art from its early days because the inspirations for early Islamic art came from Byzantium and Sassanian Persia as well as from Syria. Sassanian art was famed for its representations of court and princely activities, and this artistic tradition continued to play an important role in the development of medieval Persian Islamic culture.

Whereas Arab-Islamic artistic traditions emphasized geometric and calligraphic designs, the Persian-Islamic tradition continued to focus on scenes depicting humans and animals. During the eleventh century the Turks became the new driving force in Islam by virtue of their control of much of the Middle East, including lands that were an integral part of the Persian sphere of cultural influence, mainly Mesopotamia and the Iranian Plateau. Through these Persianized Turks, Persian artistic traditions as well as the faith of Islam spread deeply into Central Asia.

Very much like the Turks, the thirteenth-century Mongols who established the Il-khanid of Persia adopted an artistic tradition that gloried in miniature paintings portraying hunts, battles, princes and princesses drinking wine, courtship ceremonies, courtiers playing musical instruments, and a wide variety of other nonreligious scenes. In much the same manner, this Persian tradition was later adopted by the Timurids and passed on to the Mughals of India, each by and large a devoutly Muslim dynasty but each also a patron of artists who practiced a tradition of representation that deviated greatly from the more austere, abstract artistic forms that came out of the Islamic west.

—Kumi S. Martin

Ghazan Khan Leaves Tabriz from the fourteenth-century Mongol history, Jam al-Tawarkh. Mahmud Ghazan was the most prominent leader of the Mongol Il-khanid dynasty in Persia (present-day Iran). He expanded the city of Tabriz and made it into a successful capital, and also requested that his vizier, Rashid al-Din, write a comprehensive history of the Mongols, the Jam al-Tawarkh. (Corel)

Herat flourished until the arrival of the Mongols. Chinggis Khan's army invaded the eastern part of Persia in the 1220s, destroying cities and villages. Metal production in Herat appears to have stopped, and inlay technique migrated to the western regions of Persia and farther west to Syria, Egypt, and Anatolia as artisans fled to these lands.

Inlay technique reached a high point in Syria and Egypt, especially in Damascus and Cairo, during the Mamluk era, thanks to the support of wealthy patrons. Large metal objects decorated with elaborate designs known as blazons and with bold Arabic inscriptions, each decoration a proclamation of its owner's social status, were commonly produced in the workshops of these

two lands. Moreover, metallic items were often produced as propaganda to glorify rulers.

A notable feature of Persian metal production under the Il-khanids (1256–1353) and the Timurids (1370–1507) was the appearance of a distinctive Chinese influence. The availability of Chinese luxury items encouraged Muslim craftsmen to create a unique style that combined Chinese shapes and motifs with classical Islamic organic decoration and bold Arab-Islamic inscriptions.

Mosques

Mosque architecture and decoration were strongly influenced by pre-Islamic and regional traditions, as were all other forms of Islamic art. Over the centuries, many different types of mosques and other buildings were erected. In Egypt and Syria, stone was the principal material for the construction of mosques, which were also characterized by wide central aisles and multiple tiers of minarets. During the Fatimid period, mosque complexes were formed. Initially, *madrasas*, or Quranic schools, were often attached to the mosque, and later other religious buildings were added. Some had a religious or charitable function, while others were of a more nonreligious nature.

In Iraq, Iran, and a large part of Central Asia, bricks and stucco were the primary material. With the development of ceramic production in Iran, the exterior and interior of buildings were decorated with colorful tiles, and *mibrab* areas, which indicated the direction of prayer, were often extensively decorated with luster tiles.

Persian Architecture in the Il-khanid and Timurid Eras, 1256–1507

Violence and massive ruin accompanied the conquests of the region of Southwest Asia loosely known as Persia (present-day Iran, Iraq, Afghanistan, eastern Turkey, and some adjoining lands) by the Mongols in the first half of the thirteenth century and Timur-i Leng (Tamerlane) in the latter half of the fourteenth century. Notwithstanding the initial destruction, the ruling dynasties that resulted from each conquest, the Il-khanids (1256–1335) and the Timurids (1369–1506), became great patrons of the arts and builders of mosques, palaces, and other complexes on a grand scale. The result was a golden age of Persian art, including architecture.

The age of glory for Seljuk art and architecture ended with the invasion of Iran by Chinggis Khan (r. 1206–1227) in 1218. By the end of the thirteenth century, however, his successors in Southwest Asia had carved out for themselves a Mongol empire that was essentially independent of the control of the Great Khan in faraway China. Known as the Persian Il-khanids, they had converted to Islam and were fascinated with Iranian culture. Gradually and with the help of their Persian ministers, they established the foundations of a new age of artistic brilliance.

Hulegu (r. 1256–1265), grandson of Chinggis Khan and the first il-khan of Persia, rebuilt several cities and even ordered some new construction, such as a Buddhist temple at Khoy and a seat of learning in Maragha, the first Il-khanid capital, located in today's southern Azerbaijan. This complex contained the *Rasadkhaneh*, an astronomical observatory that attracted scholars from far beyond the lands of Islam, and a Christian church.

Hulega's son and successor Abaqa (r. 1265–1282) increased substantially the tempo of building and rebuilding. Around 1275 he began construction of a summer palace on a site known as *Takht-i-Sulayman*, which dated back to Sasanian times. He also established Tabriz in Iran as his new administrative capital, and he and subsequent il-khans lavished on the city a variety of superb monuments.

Ghazan Khan (r. 1295–1304), a devout convert to Islam, undertook an ambitious program of

➤ SAMARQAND

Timur was born near Kish (in present-day Uzbekistan), which he captured and turned into his first capital in 1363, renaming it Shahr-i Sabz (the Green City). The following year he and an ally took Samarqand, about 50 miles (80 kilometers) north of his capital, and in 1370 he gave Samarqand a new citadel and walls to replace those destroyed by the Mongols. In 1379 Timur ordered construction of a palace at Shahr-i Sabz, of which little remains today. Eventually, however, because Shahr-i Sabz was too remote, he moved his capital to Samarqand, an ancient city that had been a major center of trans-Eurasian commerce in the early centuries CE.

It was to this new capital that Timur ordered artisans transported from lands conquered by his armies and even from regions beyond their grasp. Sculptors, stonemasons, and stucco workers came from Azerbaijan, Isfahan, and Delhi; mosaic workers traveled from Shiraz; and weavers, glass blowers, and potters arrived from Damascus. Samarqand's major architectural projects during Timur's lifetime included the Gur-i Amir Mausoleum (ca. 1400–1404), the Bibi Khanum Mosque (ca. 1398–1405), and the Shah-i Zinda (The Living King) Mausoleum complex.

The Gur-i Amir complex includes three buildings—a mausoleum, a madrasa, and a *khanqah*, or Sufi convent—all of which are located around a square courtyard. A minaret dominates each corner of the courtyard, and rising from the mausoleum is a ribbed blue-tiled dome that is 112 feet (34 meters) high. The decoration of the entire complex, such as its tile work and architectural niches, reveals a strong Iranian influence largely because its architect came from Isfahan. The Bibi Khanum Mosque, named in honor of Timur's favorite wife, was constructed out of materials brought from India. As a result of several earthquakes, most of this structure is in ruins. The Shah-i Zinda complex was built to commemorate Qutham ibn Abbas, a cousin of the Prophet Muhammad, who came to preach

Domes of Timur's mausoleum, Gur-i Amir, in Samarqand, present-day Uzbekistan. (Konstantin Shishkin)

Islam in Samarqand in 676 and was purportedly martyred on the site the following year. Already by the eleventh century a sizable mausoleum marked the spot, but between 1370 and 1405 about 20 buildings were added. A steep walkway, which stretches some 227 feet (69 meters) upward, allows access to the main tomb. On either side of the pathway are several mausoleums, each notable for its characteristic Timurid features such as blue-tiled domes, glazed brickwork, and mosaics.

—Mohammad Gharipour

rebuilding what he termed his “ruined inheritance.” He ordered a mosque and public bath constructed in every city and dotted the major trade routes of his empire with large caravansaries to house itinerant merchants and their animals. His single most important building project was his

mausoleum, which rivaled in scale and complexity ancient Persepolis. Located at Sham, a suburb of Tabriz, the complex of buildings that surrounded his tomb contained a hospital, a library, an academy, an observatory, and a wide variety of other charitable and academic foundations.

Uljeitu (r. 1304–1316), Ghazan's brother and successor, transferred the capital to Sultaniyya (which means "imperial"), a new city on which construction was begun in 1305. Dedicated in 1313, it was dominated by his domed octagonal mausoleum, one of the supreme architectural achievements of Persia. Tragically, it is the only remaining building from this once-magnificent imperial city.

The direct line of Hulegu died out in 1335 with Abu Said Khan (r. 1316–1335), and a number of small states divided up the former il-khanate and competed among themselves for supremacy until they were all swept away in the 1380s and 1390s by Timur-i Leng (1336–1405), a man who claimed to have inherited and reconquered the Il-khanate of Hulegu.

In addition to the high level of murder, mayhem, and destruction that accompanied Timur's armies as they rampaged through lands that stretched from India to Anatolia, this Turkish Muslim warrior sent back large numbers of enslaved artisans to beautify his capital of Samarqand. The crowning achievement of this work was the Registan (Place of Sand), a large central plaza surrounded by mosques, caravansaries, and the Gur-i Amir (Tomb of the Amir), Timur's mausoleum.

The transition of the Timurid capital to Herat (in present-day Afghanistan) by Timur's successor and son, Shahrukh (r. 1405–1447), caused a shift in architectural focus. The Great Mosque and Madrasa complex at Herat, for example, built under the patronage of Shahrukh's wife Gawharshad (d. 1457), was the epitome of fifteenth-century architectural innovation. Unfortunately, as is the case with most Timurid architecture, few of the original structures remain due to wars, earthquakes, and time, but Gawharshad's richly ornamented family mausoleum is one of the fortunate survivors, a fitting resting place for a woman whose name means "luculent jewel."

Despite Herat's new prominence, the Timurids continued to build in Samarqand (and in many other cities and locales as well). One of the glories of Samarqand's Registan is the madrasa built between 1417 and 1421 by Shahrukh's son Ulugh Beg (r. 1447–1449) while governor of the former capital. This building, which faces onto

the square, was the largest and most complex structure built by the Timurids. A lover of astronomy, he also built a large observatory on the same plaza, but it no longer exists.

Under Timur and his descendants the Registan became one of the most beautiful urban squares in the world, and its buildings were some of the finest examples ever produced of typical Timurid architecture: brick structures of monumental scale with glittering polychrome exterior tile work, multiple minarets, and large bulbous domes.

Ulugh Beg ruled for only two years before he was deposed and executed by his son. Even before his death, the Timurid empire suffered numerous incursions and chronic internal unrest. After 1449 the Timurid empire was rent apart by invasions and rebellions until the dynasty was terminated in 1507. But patronage of the arts and construction of buildings went on, even in the face of declining Timurid authority. Most notable in this regard was Husayn Bayqara (r. 1469–1506), whose power was confined to eastern Iran and the capital of Herat but who made his truncated kingdom a major literary and artistic center.

In addition to members of the royal family, patrons during the Timurid era included military figures, bureaucrats, and Sufi masters and their devotees. To be sure, many patrons erected palaces and pavilions as well as formal gardens, but most of the roughly 250 surviving Timurid buildings served a religious function. With increasing public interest in Sufism, newly constructed Sufi convents and tombs of Sufi saints became centers of Timurid religious orthodoxy.

Artistic Patronage under Mehmed II

Immediately after conquering Constantinople in 1453, Ottoman sultan Mehmed II (r. 1444–1446, 1451–1481), honored as “the Conqueror,” set about revitalizing the city as the seat of his power and the prestigious intellectual, cultural, and artistic capital of a world empire. This city was to become known as Istanbul or, as Mehmed punned, Islambul (“full of Islam”). Not only did

► PORTRAIT OF MEHMED II

Gentile Bellini (1429–1507) was a member of a celebrated artistic family. His most famous surviving work is the *Portrait of Mehmed II* (1480).

The calm, relaxed pose and three-quarter view of Mehmed were in keeping with Bellini’s preferences in portraiture. His addition of the three-dimensional arch heightens verisimilitude and dignity, also giving some distance between the viewer and sultan, probably an effect that Mehmed wanted. The elaborate bejeweled cloth with tulip motifs evokes Ottoman designs. The faded Latin text on the bottom left plaque probably says “Victor Orbis” (“Conqueror of the World”); the lower right plaque has the date November 25, 1480. The three-crown devices hovering above the arch probably represent the lands of Asia, Greece, and Trebizond, which Mehmed had conquered. These crowns were replicated on the reverse side of the portrait medallion that Bellini sculpted for Mehmed and with which the artist was rewarded for his service.

Bellini’s Ottoman period benefited his later work, particularly *Saint Mark Preaching in Alexandria* (1504–1507). Notably, Bellini himself is in this latter painting, proudly wearing the gold chain and medallion awarded him by Mehmed. Though his Venetian contemporaries had some familiarity with the appearance of the various Ottomans who visited and traded with the city, Bellini had a keener eye for Islamic architecture and the diversity of Muslims and Ottomans, including Ottoman women’s style of dress. His sketches from his Ottoman period were used for later paintings, most of which are lost, as well as being used by other Renaissance painters who wanted Orient-type figure drawings for their own work.

—Peter C. Valenti

Portrait of Mehmed II by Gentile Bellini. (The Art Archive/National Gallery London/Eileen Tweedy)

he see himself—and was seen by his contemporaries—as the sultan of a powerful empire, the mightiest of Turkic dynasts, and a champion of the Islamic world, he also claimed to be the heir of the great Roman/Byzantine tradition, a logical argument given his possession of Constantinople and most of the former Byzantine (eastern Roman) empire. Mehmed thus continued to promote artistic and cultural traditions derived from his Turko-Islamic heritage but also from Greco-Roman traditions. His activities included refurbishing buildings that had fallen into disrepair under the late Byzantine period, inaugurating a large building campaign, sponsoring artistic projects, and inviting and settling (sometimes forcibly) in his new capital key groups and professions, such as merchants and artisans.

Among his grandest building projects was the Fatih (Conqueror) mosque complex (built during 1463–1470); the Eyüp mosque-shrine complex (begun in 1458 and changed over time); a great bazaar complex (built in stages from 1456

onward) today called the Kapalıçarşı, or Covered Bazaar; and Topkapı Palace (1459–1479), the latter remaining the seat of government and the residence of Ottoman sultans until the late nineteenth century. He also transformed the Hagia Sophia church into a mosque (Aya Sofya). These monumental buildings, surrounded by plazas, caravansaries, workshops, and administrative buildings, fundamentally shaped the layout and visual impact of the city, a legacy still evident today amid the modern sprawl of Istanbul.

Mehmed was expanding upon established Ottoman tradition. Previous Ottoman (and Seljuk) sultans built mosques, mosque complexes (*imaret*), bathhouses (*hammam*), schools, hospitals, soup kitchens, bazaars, and merchant establishments (*khans*, or *caravansaries*), many of which had elaborate tile work and decoration. Until 1453 the most lavish Ottoman building projects occurred in Edirne and Bursa, the previous capitals of the Ottoman empire. For example, all Ottoman sultans up to Mehmed II built *imaret* in Bursa and had their tombs there. The architecture of these early years incorporated both Byzantine and Seljuk styles into broader Turco-Persian and Islamic styles. It is clear that Byzantine architecture—the best example being Hagia Sophia—continuously inspired Ottoman architects in Istanbul from 1453 onward, as the original plan of the Fatih mosque and Sultan Süleyman (Suleiman) the Magnificent’s stunning Süleymaniye mosque (1550–1557) demonstrate.

Throughout the early Ottoman period up to and including the era of Mehmed II, the predominant artistic influence in the Ottoman empire was Turco-Persian, the so-called Timurid style named after Mongol-Turco-Persian cultural traditions of empires and dynasties derived from Timur-i Leng (1336–1405), also known as Tamerlane, and his successors. In the Ottoman empire this entailed recruiting countless artisans and craftsmen from Iran or other locations farther east, such as Transoxiana and Khurasan (present-day Uzbekistan and neighboring nations).

Until the early 1500s, ceramics workshops (most famously producing underglaze-painted blue-and-white tiles) were run by master craftsmen from Tabriz or other parts of Iran. For example, the earliest large-scale architectural tile decoration is found in the Yeşil mosque and tomb

complex of Mehmed I in Bursa (1419–1424), with the tile work signed by the “Masters of Tabriz.” Once Istanbul became the new capital, these masters moved there and, under Mehmed’s patronage, expanded operations. Their extensive work is evident in the Fatih mosque, as well as in the pavilion called Çinili Köşk (1472) at Topkapı Palace. Over time, the apprentices in these workshops, natives of the Ottoman empire, advanced to take over the workshops and/or open new ones; by the late 1400s the city of Iznik (formerly Nicaea) became a major ceramic production center. In addition, Mehmed strengthened the long-established tradition of the Ottoman dynasty of fostering silk and textile manufacturing (in Bursa) and carpet workshops (in Uşak); many such workshops were later opened in Istanbul. The Ottoman empire’s status as a terminus for the Silk Road meant that doing so held artistic and economic imperatives.

The Ottoman record of patronage of the Timurid tradition is further evidenced in Mehmed’s recruiting of the Uzbek court painter Baba Nakkaş and Ali Kuşçu the astronomer from Tabriz (credited with revolutionizing Ottoman astronomy and influencing Copernicus). Mehmed’s scriptorium and chancery employed many men immersed in the Timurid tradition; one such was the famous calligrapher, anatomist, and book-binder Giyas al-Din of Isfahan. Like preceding Ottoman sultans and other Turkic dynasties, Mehmed’s court patronized numerous Persian poets and musicians.

As with earlier Ottoman rulers, Mehmed commissioned manuscript books and translations. Topkapı contained many illuminated manuscripts, mainly Persian but also western European and Chinese. The value given to art is demonstrated by the fact that upon capturing the Turkmen prince Yusufca Mirza in 1472, Mehmed demanded that his ransom be paid in manuscripts and pictorial albums. His court collected the major works of the Arabic, Persian, and (various) Turkic canons but also significant works in Hebrew, Greek, and Latin. Mehmed was particularly interested in historical and geographic works from the classical Greek tradition, including the *Iliad*, and biographies, especially of Alexander the Great. Mehmed had not only Arabic, Persian, and Quranic tutors but also Greek and Latin tutors.

Seeing himself as the inheritor of the Roman/Byzantine empire and classical tradition, Mehmed gave strong demonstrations of his knowledge and admiration of the Greek heritage during his visits to Athens in 1458 and Troy in 1463 (partially explaining why he had the Parthenon converted into a mosque by 1460). He even collected classical sculptures.

Mehmed hired the services of the Bolognese architect and engineer Aristotele Fioravanti and the Florentine architect Filarete. He also repeatedly requested the services of painters, sculptors, and carvers from various Italian city-states. The most famous was the 1479–1481 visit of the Venetian painter Gentile Bellini. Bellini was the greatest artist of his time in Venice, and so his visit to Mehmed was both a major artistic exchange and of great diplomatic significance. While there Bellini executed a series of paintings and bronze medallions, though only two paintings of this period survive: the *Portrait of Mehmed II* (1480) and the *Seated Scribe* (1479–1481). While the Ottoman empire, and the Islamic world in general, had a rich tradition of miniature painting and portraiture (the latter primarily Persian), Mehmed's patronage of Bellini represented an encouragement of Italian Renaissance portraiture, not necessarily embraced elsewhere in the Middle East. Nevertheless, both of the above Bellini paintings were later emulated by Ottoman and Persianate painters.

Japan's Indigenous Aesthetic

After an intense phase of borrowing in which Japan remade itself on the model of the great civilization of China, by about 1000 an indigenous style emerged as the Japanese synthesized and modified imported ideas and institutions. Japan's hybrid aesthetic continued to evolve over the next five centuries, informing all aspects of culture from language and literature to art and architecture. Hints of a native approach to artistic design and expression were apparent much earlier in the asymmetrical Jomon pottery (the world's oldest, dated well before 10,000 BCE) or in Yayoi-period wooden buildings (ca. 300 BCE), with their distinctive construction details and roof design. Furthermore, awareness and nascent standards of what was beautiful were evident in the awe toward nature of the domestic Shinto religion. These enticing signs of Japan's indigenous artistic sensibility were then swamped by the massive wave of Chinese culture from the mid-600s. The initial conduit of learning from China was the Indian religion of Buddhism, initially imported via Korea. Buddhism not only brought with it religious texts and artwork but also opened the way for a flood of Chinese things, including written language, governmental institutions, and continental styles of gardening and architecture and further forms of Buddhism. The heyday of borrowing from China was delineated by a series of 12 official embassies dispatched directly to the Chinese capital in the period 630–837. Following the end of these tributary missions—and the dynastic decline of Tang China (618–907) in the mid-eighth century—the Japanese turned inward to digest and revise the vast knowledge acquired from China. After two centuries of relatively indiscriminate emulation of all things Chinese, there came a time of more selective borrowing and a reinterpretation of previously imported culture.

By the middle of the Heian period (794–1185), Japanese culture had come into its own as a discrete and recognizable entity, defined by elevated standards of beauty and behavior. The emergence of a native style also involved the written language. While both Chinese and Japanese poetry remained popular, the real innova-

tion in language and literature during the Heian period was a vernacular literature written in a mixture of Chinese characters and a phonetic syllabary expressing the sounds of spoken Japanese. This new literature was all the more revolutionary because it was invented by the ladies-in-waiting of the Heian court. Key works of Heian literature included Murasaki Shikibu's *Tales of Genji*, the world's first psychological novel, and Sei Shonagon's *Pillow Book*, an acerbic commentary on the love lives and behavior of the Heian aristocracy. Both works reflected the rarified culture of the Heian court and its standards of what was beautiful in clothing, appearance, and artistic and spoken expression.

Along with the appearance of new sects of Heian Buddhism, religious art became recognizably Japanese (especially wooden sculpture, in contrast to China, where the medium was typically stone). Religious art was joined by the new brightly colored Japanese-style painting and, by the late Heian era, hand-scroll paintings, such as the famous illustrated version of the *Tales of Genji*.

There was no continental prototype for one feature of the Heian age: the growing power of samurai warriors, who grasped control of the country following a brief civil war during 1180–1185. The first artistic output of the ensuing Kamakura period (1185–1333) consisted of war tales, such as *Tales of the Heike* describing the poignant fall of the relatively effete and aesthetically sophisticated warrior clan of Taira in the war of 1180–1185. Another new development was the expansion of Zen Buddhism, with its stress on individual enlightenment and seated meditation, to meet the spiritual needs of the active warrior class, thereby supplanting the elaborate rituals of classical Mahayana Buddhism. Following the lead of the earlier Heian period, Japanese indigenous artistic expression became increasingly independent from Chinese models, especially in painting and sculpture. Particularly innovative was the Zen monk Unkei, whose lifelike sculptures were crafted of multiple solid wood blocks and painted bright colors.

Under the second samurai government, during the Muromachi period (1336–1573), there came a renewed interest in China, not so much

➤ SESSHU TOYO—ARTIST TO THE MERCHANT CLASS

Sesshu (1420–1506) was the epitome of a Zen Buddhist monk-artist. While a young man at Kyoto's Sokoku-ji, Sesshu first encountered many works of fine art, especially monochromatic ink paintings of China's Song dynasty, that became models for his own work. He also became a student of Shubun, one of the great artists of the day, although Sesshu displayed more independence from shogunal control than his teacher. (In this sense, as his patrons were more of the merchant than the warrior class, even though Sesshu was born into a samurai family, one can refer to him as an artist to the merchant class.)

With the outbreak of war in Kyoto in 1467, Sesshu fled westward and then on to China, where he studied Buddhism and journeyed to famous scenic places such as West Lake, although he found no living master to serve as his teacher in China. Upon his return to Japan he produced his most famous works from his studio in Yamaguchi. His characteristic style involves brushwork akin to calligraphy, influenced by Zen in its abbreviated or suggestive use of sparse lines to suggest deeper content or meaning. His masterpiece, the *Long Scroll of the Four Seasons*, depicts a landscape through the climatic changes of a year. Six paintings attributed to Sesshu are ranked among the National Treasures of Japan.

—Lawrence Fouraker

to emulate the contemporary Ming dynasty (1368–1644) as to acquire artwork and knowledge from previous dynasties, especially the Song (960–1279). Popular imported Song artwork included calligraphy, ceramics, lacquer, and, above all, monochromatic ink landscape paintings. Many great Muromachi artists were Zen monks, and especially in ink painting one can infer an ascetic discipline in the monochromatic limitation of artistic expression. A similar influence of Zen is apparent in the withered landscape of dry rock gardens, expressing the image of water in its absence, such as the garden at Ryoanji Temple, composed of 15 rocks in a field of raked sand. Zen influence was likewise apparent in the classic tea ceremony, linking art, religion, and

architecture in new ways. Rustic small tea huts constructed of natural materials focused one's concentration on the act of preparing and consuming tea. The tatami floor matting, sliding doors, decorative alcove, and generally sparse decoration of these huts remain the model of a traditional Japanese room to this day. The intentional limitation of the materials used and the avoidance of ostentation is one by-product of the Zen aesthetic, although the stress on simplicity did not deny a countervailing tendency to prize and collect precious tea ceremony implements and artwork, particularly the outwardly rough tea bowls that were the center of the ceremony. And so in the midst of internecine samurai warfare on a new scale, we find yet another stage in the ongoing development of the indigenous Japanese aesthetic sense.

The Buddhist Monuments of Pagan

Pagan, the capital city and religious center of the kingdom of Pagan that dominated central Burma from roughly 1044 to about 1287, contained several thousand religious structures, all devoted to furthering the Law of Theravada Buddhism.

The religious buildings of Pagan were of five different types: temples, stupas (see below), monasteries, other religious structures (such as the Pitaka-taik Library, which housed Buddhist sutras), and underground or half-underground monasteries, or image houses, that recall the cave temples of India, such as at Ajanta and Ellora.

The most common type of temple was square with one central chamber (the shrine, which contained a statue of the Buddha) with either one entry or a central core with a corridor (ambulatory) around the core; a variation of this was a round structure with a round or square central chamber. A second type consisted of two parts: a smaller four-sided or quasi-octagonal structure attached to a larger one, the smaller part an entrance hall and the larger part the shrine; another type was similar except that the larger section had a central core with a corridor around it. A number of other variations existed, including five-sided temples on a pentagonal base. Apparently unique to Burma, the incentive for the development of monuments of this sort was the desire to honor the five Buddhas of the present cycle of time: Krakuchanda, Kanakamuni, Kasyapa, the historic Buddha Gautama, and the future Buddha Maitreya. Today 15 temples in this unique form exist amid Pagan's 2,217 registered monuments.

The stupa (in Burmese *zeidi*) originated in India as a domed structure that housed deep within it a relic of the Buddha or his Companions (such as the Great Stupas at Sarnath and Sanchi),

Buddhist stupas at Pagan in present-day Myanmar (formerly Burma). Pagan was the capital of Myanmar from 1044 to 1286, during which time the stupas were constructed. There are more than 10,000 temples and other religious structures scattered across the plain at Pagan. (Jeremy Edwards)

but in time it came to be any free-standing domed structure of veneration that especially attracted pilgrims. Burmese stupas consist of five main parts: the base, three stepped terraces, the bell (the main part, or body), a spire tapering upward, and the umbrella (a series of parallel disks around a pole) at the top of the spire. The body of the stupa, which in India was originally a hemisphere, supposedly represents an overturned alms bowl (although its origin can be found in pre-Buddhist funerary tumuli), and the spire, in its earliest form a smaller hemisphere with flattened bottom, represents an overturned drinking cup.

Monasteries varied greatly in design, but all followed two basic forms. One design is illustrated by the So-min-gyi-ok-kyaung Monastery, which had 11 rectangular cells (the individual rooms in which monks lived and meditated) around a courtyard, each with a window in the outer wall; a shrine on one side of the courtyard; and an entrance hall on the opposite side. There was originally an upper story, but all that now remains is another smaller shrine above the main one. Another monastic complex, Hsu-taung-pyit, exemplifies the second basic design. It is a spacious square enclosure inside of which there is an inner walled area around the main residence with a temple in one corner of the enclosure; placed in rows within the open space were 38 or more small subhouses where monks, novices, and servants resided, 10 of which are still standing.

➤ THE TEMPLE PAINTINGS OF PAGAN

In spite of the passage of more than 700 years since the fall of the kingdom of Pagan, when the construction of new Buddhist monuments was almost entirely brought to a halt, frequent earthquakes, which reduced many monuments to mounds of brick rubble, vandalism (including the wholesale removal of some of the finest mural paintings for sale in Europe and the defacing of paintings with graffiti), and the continued “refreshing” of those temples still in use by the application of successive coats of whitewash over underlying older decorations, many important paintings remain in remarkably good condition and are presently being maintained and restored.

Some of the paintings’ subjects of greatest interest are entrance guardians, the Buddha and his disciples, the attack and defeat of the army of Mara (the Evil One), the robing of Queen Maya (mother of Siddhartha Gautama, also known as Sakyamuni, the historical Buddha), the nativity scene of the Buddha, Gautama’s tonsure, and the ascent (of Gautama) to Buddhahood, as well as figures of various Hindu/Buddhist deities (such as Brahma, Shiva, Vishnu, Indra, and Sarasvati), bodhisattvas, dancers, drummers, and celestial musicians (*apsarasas*), and scenes from *jatakas* (stories of the former incarnations of bodhisattvas, especially of the historical Buddha).

The Glory of Byzantium

Between 1025 and 1204 art, architecture, ritual, and culture (of great brilliance) displayed Byzantine imperial ideals and orthodox Christian beliefs to a world that extended far beyond the geographical boundaries of the empire. Even as the empire failed in its last centuries, from 1261 to 1453, its arts and literature flowered and outlasted it by more than a century. Between 1000 and 1500 Byzantine culture extended, in different ways, to the Islamic world, Latin Christendom, and the emerging polities of southeastern Europe, Russia/Ukraine, and northern Eurasia. Byzantium’s influence can still be seen in churches and monasteries, icons, manuscripts, and luxury goods that have survived in widespread locations.

Recent scholarship also underlines the contributions of Byzantine learning, less immediately accessible to modern sensibilities, to intellectual developments in neighboring civilizations. Byzantine art and culture, now mostly viewed through widely scattered museum objects, reflect a world where emperors, churches, monasteries, and an unrivalled treasury of sacred art and relics offered a compelling vision of the divine order (*taxis*) on Earth.

Orthodox Christianity permeated Byzantine culture, and the ninth-century restoration of icon veneration initiated the development of new forms of architecture, liturgy, and religious images that filled churches, imperial buildings, public spaces, and private homes. Churches and monasteries, generally domed structures of modest size, were covered with golden mosaics and frescoes culminating in an image of *Christos Pantokrator* (Christ, Ruler of All) at the apex of the central dome. A screen, eventually covered with icons (the iconostasis), separated the worshipper from the sanctuary and enhanced the holiness of the Eucharist. Icons, portable images of holy figures, were central to public and private worship. Orthodox believers regarded each not as a painting but as the focus for reverent communication with the holy figure spiritually present in the image. Late Byzantine icons of the fourteenth and fifteenth centuries, less stylized than earlier sacred images, conveyed increased emotion, humanism, and a sense of the immanence of Christ and Mary to the individual worshipper. As candles, incense, and liturgical chant reflected the mosaics and images in the liturgy, the Byzantine worshipper had an intense experience of the ordered reflection of Heaven. Its heritage survives today in monasteries at Mt. Athos, Mt. Sinai, and Meteora. The same elements in imperial ceremonies reinforced the emperor's role as protector of divine order, and although surviving remains are fragmentary, visitors' descriptions convey their impact on aspiring cultures.

Byzantine sacred and imperial culture had its most profound influence on the peoples of Eastern Europe and northern Eurasia, a world that has been described as the Byzantine Commonwealth. Beginning with the ninth-century missions of Cyril and Methodius, Byzantine Christianity was adopted by rulers of the Bulgars,

Serbs, Rus, and other peoples, to whom it offered a model of divinely ordained rule. In the wake of conversion, Byzantium's sacred learning and artistic expressions were adapted to the cultural environment and languages of the Slavic world. Translations of Greek Christian texts into the alphabet and vocabulary created by Cyril's disciples for the South Slavs in tenth-century Bulgaria (Old Church Slavonic) were later adapted to the East Slavonic language of the Rus and formed the basis of written culture throughout the Slavic regions of Orthodox Christianity (whereas other Slavic Christians, such as the Poles, followed the Latin traditions and culture of the Roman Church). Byzantine artists, craftsmen, and copyists were sent to Slavonic rulers and monasteries to train local craftsmen, producing monuments such as the cathedral of Sviata Sofia in Kiev in the twelfth century, late medieval Serbian monasteries and frescoes, and the rich Russian tradition of icon painting. The monasteries of Mt. Athos in northern Greece, representing all Orthodox cultures, served as a spiritual and textual community. Long after the fall of the Byzantine empire the concept of a Byzantine order remained, and the orthodox rulers of Moscow claimed to be its successors in the so-called Third Rome.

Eastern Christian communities and monasteries in the Islamic world, from Syria to Egypt, Ethiopia, and Nubia, were important centers of religious and cultural exchange. Their manuscripts, frescoes, and icons demonstrate continued Byzantine interaction with native traditions and, frequently, the presence of Byzantine artists and copyists. The Greek monastery of St. Catherine in Sinai, which has maintained an unbroken tradition of worship since the sixth century, was a pilgrimage destination for Byzantine Orthodox, Armenian, Syrian, Coptic, Ethiopian, and Latin worshippers and today houses the greatest existing collection of Eastern Christian manuscripts and icons. Its multilingual manuscripts and the extraordinary quality of its images reflect the importance of pilgrimage as a vehicle for intellectual and artistic communication across linguistic and theological divides. Despite religious and political antagonism, Byzantine and Islamic courtly culture and ceremony, trade, and scientific learning were vehicles for

► VENICE AND KIEV

The cities of Venice, Italy, and Kiev, Ukraine, had deep connections with Byzantium that can still be seen in their principal churches. In Venice, San Marco, initially the doge's chapel (and later the state church), was modeled in the eleventh century after the five-domed cross-in-a-square Church of the Apostles in Constantinople (the imperial mausoleum) but adapted to Latin liturgical needs. Its walls were covered with mosaics first completed between the eleventh and thirteenth centuries by Byzantine masters and the Venetian mosaicists they trained in a Byzantine program that became progressively Italian as the structure was completed and restored over the centuries. San Marco was filled with Byzantine objects, including the core of its early-twelfth-century gold enameled retable, or altarpiece, the Pala d'Oro (the Golden Altar Cloth). In the thirteenth century when the Fourth Crusade filled San Marco with treasures ranging from marble pieces and mosaic tesserae (fragments) to the famous bronze horses mounted on the basilica's facade, it became a showplace for Byzantine arts. San Marco is a unique reflection of the city's relationship with Byzantium, first as a source of artistic and cultural inspiration for the doges and later as a showplace for objects that made it a museum of Byzantine art.

Prince Iaroslav (1036–1154), ruler of eleventh-century Kiev, also modeled his capital on Constantinople, including a Golden Gate like that of Constantinople. He brought Byzantine artists and craftsmen to build a new cathedral of St. Sophia in the Byzantine style and fill it with mosaics and frescoes, often using imported materials. With its Christ Pantokrator, mosaic inscriptions in Greek,

Mosaic depicting the transfer of the body of Saint Mark at the Basilica of San Marco, Venice, Italy, thirteenth century. (Elio Ciol/Corbis)

and scenes of the Constantinopolitan court, St. Sophia was a Byzantine church. Iaroslav's successors built other churches at nearby monasteries, notably the golden-domed church of the archangel Michael, using Byzantine craftsmen who taught their arts to Kievans. Kiev's churches were plundered, remodeled, and destroyed over the centuries, so only St. Sophia's interior preserves its original Byzantine work today.

—Dorothy de F. Abrahamse

cultural exchange. Byzantine luxury goods such as silk were prized for their quality as diplomatic gifts and trade items, and recent studies have shown an ongoing cross-fertilization of Byzantine and Arabic learning in subjects such as astronomy, astrology, dream interpretation, and medicine.

Current scholarship underlines the complexity of Western appropriation of Byzantine art and culture, extending well beyond the fall of the empire and throughout Europe. Latin Christians, despite theological differences, prized Byzantine

icons, architecture, and relics. Through the twelfth century Europeans encountered Byzantium in Venice, where San Marco was built and decorated as a Byzantine-style cathedral, and in formerly Byzantine southern Italy, whose Norman cathedrals such as at Palermo displayed Byzantine mosaics on a grand scale. Greek monasteries survived in southern Italy, but it was not until the fifteenth century that humanist scholars sought their manuscripts as sources of learning.

The crusades and Western European trade colonies in the eastern Mediterranean exposed

Byzantine culture to the West. Artists in the crusader states collaborated with their Byzantine counterparts, but the encounter of Byzantium and the Latin world was dramatically changed by the conquest of Constantinople in 1204. Looted relics and other treasures of Constantinople were dispersed to Venice, Rome, and northern Europe, where they inspired awe. Although many of the Byzantine art objects in Europe can be traced to this source, their direct artistic impact is still debated. Byzantine images, however, became central to the growing individual devotion of the European late Middle Ages. Mendicant friars, especially the Franciscans, adapted Byzantine images as a focus of their spirituality, while Latin rule in Cyprus and Crete created centers of artistic cross-fertilization and image production for a growing Western market. Their impact can be seen in Renaissance art from Venice and Florence to the Flemish masters. Byzantium's other great contribution to Western European culture, the transmission of classical and Christian Greek texts, depended on access to language and manuscripts. Both were brought to the West in the fifteenth century by Byzantine émigré scholars, who brought manuscripts to Western libraries, taught Greek (although some learned persons in the West had mastered Greek in the preceding centuries), and published and translated classical Greek texts for humanist scholars and their patrons who based the so-called Renaissance on their supposed recovery of classical learning.

Traditionally the glory of Byzantium has been seen in the periods of its greatest political strength, the Justinianic (527–565) and Macedonian (843–1025) eras.

Byzantium's enduring heritage, however, was certainly the transmission of ideas and beliefs through images and words to the medieval and early modern worlds, and these expressions reached their fullest development in Byzantium between the eleventh and fourteenth centuries. The process of appropriation was always complex and interactive, varying from the formative influence of Byzantine Christianity and the creation of Slavonic literature in the "Byzantine Commonwealth" to the more focused use of Byzantine scholars in the Italian Renaissance. The brilliance of Byzantine culture in Constantinople can only be reconstructed in the imagination,

but its elements are powerfully conveyed in its refractions.

The Art of Latin Europe—Cathedrals and Ivories, Tapestries, and Reliquaries

The term "Gothic Architecture" conjures the image of an enormous medieval European stone church containing religious images in stained glass, stone sculpture, fresco, and carved wood. Existing exemplars draw pilgrims and tourists worldwide and are easily accessible online. York Minster in northern England, the largest Gothic cathedral in northern Europe, was built over a span of 250 years beginning in the 1220s. It is 486 feet (148 meters) long and 223 feet (68 meters) wide, rises 184 feet (56 meters) to the wooden vaulting inside the tower, and presents a variety of architectural styles.

In 631 Pope Honorius I made York the northern ecclesiastical capital of the Roman Church established in Britain. A stone minster (mission) built to house the cathedra (bishop's seat) in 670 was replaced by a Norman church in the 1070s. In 1227 its clergy made a successful argument in Rome for the canonization of Archbishop William Fitzherbert (d. 1154). The saint's relics were transferred to a new shrine behind the high altar in 1284, in the presence of King Edward I. William's head, kept by itself in a reliquary covered in silver, gilt, and jewels, was the cathedral's out-

► REPRESENTATIONS OF THE VIRGIN MARY

Portable devotional objects for the wealthy, such as Paris's mid-thirteenth-century, ivory *Sainte-Chapelle Madonna*, carried details that recalled the monumental sculpture common to both Romanesque and Gothic cathedrals. The curved stance of this Virgin, which places one hip higher than the other to support the child, is a result of the demands of working with elephant ivory. The best carvers, who often worked in wood as well, were able to combine the demands of material and style, capitalizing on the curve of the tusk and the patina of the ivory and then adding touches such as vivid lapis lazuli paint for the eyes of the Virgin.

In Carlo Crivelli's *Annunciation with St Emidius* (1486), the Virgin is bent over a book as light from Heaven strikes her forehead. Gabriel, on his way to visit her, has stopped to talk with Emidius, the patron saint of Ascoli, Crivelli's hometown. The saint carries a detailed model of the city, which gained its rights of self-government on the Feast of the Annunciation in 1482. We can peek through the doorway to see Mary's room. Traditional elements of portraits of the Virgin, such as the dove and light as reminders of the Incarnation, the liquid draperies of Romanesque and Gothic statues, and the prayerful folded hands of the leaning figure, recall the medieval devotional context as vividly as the architecture reaches further back into the Roman past. But the focus of the painting is on the lovingly detailed material luxuries that surround the beautiful young girl. They announce, as Lisa Jardine has noted, "Italian access to markets from northern France to the Ottoman Empire," showing rugs from Constantinople, tapestry from Arras, glass from Venice, metalwork from Spain, porcelain and silk from China, and broadcloth from London. The Virgin presides over Europe's successful Mediterranean

St. Chapelle Madonna, French, about 1250. (Scala/Art Resource, NY)

trade and becomes symbolic, in her youth and beauty, of a luxury that is housed in Renaissance buildings that recall Italy's classical Roman past.

standing attraction, brought out for King Henry VII's daughter to kiss on a state visit in 1503. Pilgrims, hoping for miraculous healings, followed these royal visitors. Christian altars were sanctified by the relics of saints, which became the church's most valuable possessions, and their containers proclaimed their importance and their connection, through the saint, to eternal glory and the power to heal.

Pilgrimage brought visitors who made offerings to the church and spent money in the city. Their presence combined with local needs to create a constant demand for books, paintings, reliquaries, tapestries, liturgical dress, altar furnishings, and a host of other objects beyond the stone and glass of the building. Administration, pilgrimage, and local or regional markets made cathedral cities part of a network of medieval

travel, open to foreign influences from as far away as Byzantine Constantinople and Islamic Alexandria, which acted as middlemen for goods from Asia, or the coast of Africa, where by the thirteenth century the Swahili trade corridor supplied ivory for the reliquaries and altar furnishings of European churches. Just as the texture and shape of elephant tusks were worked into the ivory forms of the Madonna and Child, so the network of trade and travel affected the design of medieval churches and their furnishings.

In the mid-twelfth century the massive pillars and walls of the Romanesque style, a fortresslike design based on the Roman basilica but roofed in stone instead of wood, gave way to thinner walls used as frames for stained glass. An innovation in vaulting and the use of flying stone buttresses allowed Abbot Suger (ca. 1081–1151) of the abbey of St. Denis near Paris to radically increase the size of windows in his church and to use them to display brilliant colored glass designs. Like the ornamental sculpture that turned buildings into stories to be read by the initiate, the glass offered a medium for symbol and narrative. This new Gothic (or northern European) style overwhelmed the viewer with a light that shifted with the outside illumination and constantly demanded attention to pictures of events in the Gospels or from the lives of Old Testament prophets and kings, all conveyed in brilliant color on massive canvases of glass. Canterbury, York's rival as the chief cathedral in Britain, was rebuilt in the new style in 1175, part of a trend that some scholars have called International Gothic by the time of its greatest influence in the late 1300s. York itself, rebuilt almost a century after Abbot Suger's innovations, participated in Romanesque, in Gothic, and in a number of other styles identifiable in not just church construction but also in the design of other buildings and objects in Europe during the medieval era. Gothic can be seen as a set of values in architecture that came to permeate all media large and small. Objects such as portable ivory statues imitated larger Gothic statuary, for instance. Such small luxury items circulated widely, allowing people access to the new style in art as they appreciated the texture and patina of the ivory.

A Revolution in Artistic Perspective—Early Renaissance Painting, Sculpture, and Architecture

In late medieval and early Renaissance Europe, a change in the artistic world that began with the twelfth-century northern European revival of interest in Roman art and architecture was taken to new heights by the artists and architects of Italy and particularly those of Florence. In order to understand how this came about, it is important to understand Renaissance humanism and its scholars.

Fourteenth- and fifteenth-century Florentine poets, historians, and political theoreticians such as Francesco Petrarca, Coluccio Salutati, and Leonardo Bruni, building upon the work and enthusiasms of twelfth- and thirteenth-century predecessors, focused their energies on reviving the humanistic, that is the literary, traditions of classical Roman antiquity. To attain this goal, they and others set out to find ancient Latin manuscripts that had remained in obscurity since the early medieval period. Rooting through monastic libraries and other obscure places, these scholars brought to light almost-lost works of such important literary figures as Cicero, Horace, and Virgil. Of equal importance, they also discovered some mathematical and architectural works, the ancient Roman Vetruius's architectural theory being the most influential of these rediscovered texts. But what did the humanists' revival of ancient literature and mathematics have to do with a revolution in the world of art?

➤ WHAT IS PERSPECTIVE?

Perspective is an artistic technique that adopts principles of geometry to trick the viewer's eye into thinking that a two-dimensional painting or drawing is three-dimensional. In order to make this illusion work, an artist must place a fixed point, called a vanishing point, on the canvas or fresco. Once a vanishing point is determined, all parallel lines in the painting must intersect and end at that determined point.

The vanishing point in Masaccio's *Holy Trinity* is just below the cross on which the crucified Christ hangs—actually, on top of the first step upon which the two patrons who commissioned the fresco sit in prayer. The result is that the viewer is drawn into the scene.

Of equal importance, Masaccio created a light source (shining in from the right side of this fresco) that illuminates and gives his figures sculptural volume. When linear perspective and a light source are used together, the effects are stunning, and the illusion of three-dimensionality is striking.

—William Landon

Masaccio's Holy Trinity, about 1425 CE, S. Maria Novella, Florence, Italy. (Scala/Art Resource, NY)

In the early Renaissance period there was no distinct separation of disciplines. A Florentine humanist could be a well-versed mathematician, a poet, and an artist all at the same time. Indeed, when these various disciplines were brought together, a revolution was introduced into the world of Florentine art: the discovery of perspective, a blend of artistic creativity and mathematical precision.

Several Florentine artists were associated in special ways with the discovery of perspective: Brunelleschi (ca. 1377–1446), Donatello (ca. 1386–1466), and Masaccio (ca. 1401–1428). Brunelleschi is known for his architectural designs, Donatello for his sculptures, and Masaccio for his paintings. We will focus only on Masaccio because his work brings together Brunelleschi's architec-

tural talent and Donatello's careful sculptural eye in a single painting, the *Holy Trinity*.

Scholars are not sure of the exact year in which Masaccio painted the *Holy Trinity* and date it anywhere between 1425 and 1428. That painting, more specifically a fresco (a mural painted into fresh wet plaster that bonds with the pigments as it dries), is located in the Church of Santa Maria Novella in Florence. A brief description of the painting illustrates its originality and its revolutionary qualities.

At the center is a realistic depiction of the crucified Christ. Standing behind Christ is God the Father, whom Masaccio depicts as somber and regal; flying between God the Father and the God the Son is a snow-white dove, which, in the Christian tradition, represents the Holy

Spirit. This iconographic depiction of the Trinity was not, in and of itself, unusual or revolutionary, but the setting was.

The Trinity is situated in what appears to be a three-dimensional world, and here the revolution of mathematical perspective is felt most keenly, for the Trinity appears to exist in a real environment. Indeed, the viewer feels that it is possible to reach into the space in which the Trinity is depicted. The architectural detail of the painting's vaulted ceiling, which reminds us of one of Brunelleschi's buildings, is almost tangible, and the almost sculptural detail of the painted figures, which bring to mind statuary such as Donatello's *David*, trick the viewer's eye into thinking that the fresco is a window in the church's wall, a window that opens straight into Heaven where the Trinity dwells. The three-dimensional illusion that Masaccio's fresco creates is nearly perfect, and such an illusion would not have been possible without the discovery of perspective.

When the *Holy Trinity* is compared with earlier religious masterpieces that are strikingly two-dimensional, it becomes clear that Masaccio's painting represents the culmination of Renaissance humanism and a work of rare and unprecedented genius, a new perspective in Western art.

Sacred Architecture in Mesoamerica

The beginning of the so-called Postclassic period in Mesoamerica (ca. 900–1521) is marked by the fall of the great city-states and empires such as Tikal and Copán in the Maya area and Teotihuacan in central Mexico. While the reasons for the collapse are still debated, it is undoubted that major readjustments occurred in all aspects of Mesoamerican society: political arrangement, economic interdependence, and, not least, religious beliefs.

An iconic figure of this period is Ce Acatl Topiltzin Quetzalcoatl (Our Lord One Reed Feathered Serpent), a king and priest who lived in central Mexico at the end of the tenth century. Historical sources dating to the time of the Spanish conquest relate stories of a man from the city of Tollan (or Tula) who left this great town to go to the land of the east. There he had an encounter with the Sun God. Ce Acatl Topiltzin eventually came back to Tula and spent the rest of his life as a ruling priest. Although he was a historical character, his significance transcended mere political or ruling abilities. In late Mesoamerican lore he became a cultural hero, credited with the invention of writing, philosophy, metallurgy, and medicine. Ce Acatl Topiltzin's attribute of Quetzalcoatl further underscores his divine character. The feathered serpent has been part of Mesoamerican lore since the first millennium BCE. He is the god of the whirlwind, which clears the sky before rain comes. It may be that Ce Acatl Topiltzin had a special ability to transform himself into the deity for the propitiation of agricultural fertility.

The most striking manifestation of the relationship between the historical figure and the deity is found in major archaeological sites, mostly pyramids, that may have served the purpose of glorifying the priest after death. In the city of Cholula, in central Mexico, rises the largest structure ever built in the ancient Americas. While the pyramid, known as Tlachihualtepetl (man-made mountain), was initially built in the Late Formative period (around the beginning of the Christian era), since the early Postclassic period (950 CE) the city was consecrated to the cult of Quetzalcoatl. It is hypothesized that Cholula was in fact Tollan, the city of origin of the historical Quetzalcoatl. The great site of Chichén Itzá, in the Yucatán Peninsula, shows a great deal of central Mexican influences both in the style and iconography of its major buildings. Most notably, the pyramid of Kukulcan (Quetzalcoatl in Yucatec Maya) is accessible on four sides, similar to the Cholula pyramid, and is decorated on every side with large feathered serpents descending from the top to the base of the structure along large stairways. Other "central Mexican" buildings at Chichén Itzá are the impressive I-shaped ballcourt (the largest in Mesoamerica), a skull

► HOW FAR DID THE INFLUENCES OF MESOAMERICA SPREAD?

Flourishing between 900 and 1400 in the American Southwest and in the basin of the Mississippi River are the sites of the first native North American civilizations that practiced a sedentary life, inhabited large settlements, cultivated maize, and engaged in long-distance trade. Cahokia, in southern Illinois across the river from St. Louis, is the largest and presumably most important site of the Mississippian civilization. Its large platform pyramids (or mounds), built within enclosures (or plazas), make Cahokia similar to the great pyramid compounds of central Mexico, such as Cholula. Around the same time, the ancient Puebloan people, or Anazasi, began building large structures around Chaco Canyon, in northwestern New Mexico, and Mesa Verde, Colorado. The rise of these native North American cities coincides chronologically with the Toltecs to the south, raising the question of which way influences were

flowing. Quetzalcoatl and the city of Cholula in particular were sacred to the merchants, and it is well known that long-distance trade, especially in conch shells and turquoise, constituted a major means of elite aggrandizement in Mesoamerica and the American Southwest and Southeast. Large caches of these materials were found in burials associated with high status. Fine attires included large ear spools, winged costumes, and conch gorgets, similar to those found in Mesoamerican elite burials.

Oral and contemporary traditions among the North American Indians show striking similarities with Aztec mythology and beliefs as they were recorded by Spaniards in the sixteenth century, yet the relationship may in fact be much older, dating to the Archaic period (10,000 BCE).

—Alessia Frassani

rack platform (known as Tzompantli in Nahuatl) for the placement of the skulls of sacrificial victims, and the Temple of the Warriors, which bears a striking resemblance to a platform pyramid at Tula in central Mexico. It is possible that the place to the east that Ca Acatl Topiltzin visited in his journey was indeed the Maya city of Chichén Itzá. Apotheosized after death, this legendary priest became the main god, under the name of Quetzalcoatl/Kukulcan, in early Postclassic Mesoamerica.

When the Mexica gained power in central Mexico a few hundred years later, they still recognized the great legacy of the Toltecs (people from the legendary Tula) and its leader. The political ideology of the Mexica, however, revolved around the cult of their patron deity Huitzilopochtli, under whose guidance they entered the Basin of Mexico and founded their capital city, Tenochtitlan, on a lake. Found at the site of modern Mexico City, Tenochtitlan was designed around the so-called sacred precinct, an area that included the most important shrines. The Mexica continued the Toltec tradition of building skull racks and ballcourts. The most important monument was, however, a double pyramid dedicated to the rain god Tlaloc and the Mexica

patron deity Huitzilopochtli. Worshipped in two distinct shrines on top of the pyramid, they expressed the double nature of late Mesoamerican religion. While Tlaloc is an ancient god of paramount importance for ensuring the continuation of the agricultural cycles, the patron deity was newly introduced in order to tie Mexica rule to the maintenance of cosmological order. This temple, known as Templo Mayor, or Heuyteocalli (“ancient temple” in Nahuatl), was conceived as the center of the universe, connecting all realms: the earth and sky vertically and the four directions horizontally. The twin temple was rebuilt at several occasions, and caches of offerings were found during excavations that coincided with several stages of construction and enlargements of this never-ending act of god worshipping.

■ Introduction: Literature and the Performing Arts— A Flourishing of Bards around the World

During years 1000–1500, the literature and performing arts of a number of cultures around the world reached new levels of creativity. In many cases, this creativity was a continuation of and expansion upon earlier traditions; in some instances, it was revolutionary.

China provides examples of both phenomena. Most of China's vast poetic output during these five centuries was a maturation of poetic forms established during the Tang era (618–907). At the same time, however, due to its dramatic rise in urbanization, expanding levels of literacy, and a flourishing book-printing industry, China also gave birth to two new forms of literary expression: the theater, which appealed to all levels of urban society, and the novel.

Given the high level of Chinese interchange with India during the Song era (960–1279), it seems likely that earliest Chinese theater was influenced by Indian drama, which had roots going back centuries to at least the Gupta era (ca. 320–ca. 550). Whatever the case, Chinese playwriting was in its infancy during the Song centuries, and very little evidence remains of these early ventures. However, building upon these modest origins, theater blossomed and bore marvelous fruit during the Yuan (1279–1368) and Ming (1368–1644) eras. Confucian scholars were largely denied civil posts by the Mongols, and this enforced retirement from public life appears to have been a prod to some to turn their hands to expressing themselves and giving vent to their frustrations by writing for the theater. Some 600 known plays were crafted during this century, of which about 160 survive today. During the Ming period, theater—plays for both elites

and the masses—proliferated across China and also splintered into a wide variety of regional forms.

The Chinese novel has roots in Buddhist stories, especially early *jataka* tales that relate the Buddha's many incarnations, and in secular short stories. The latter were quite popular and proliferated during the Song era. Neither genre, however, reached the level of complexity and narrative of a true novel. During the fourteenth century, collections of stories loosely strung together began to appear, and these were followed in the fifteenth century by true novels, most of which were set in historical or legendary contexts. Many were written in vernacular Chinese, as opposed to formal classical Chinese. One of the earliest, whose dates of origin are debated (anywhere from the fourteenth century to the latter half of the fifteenth century), was Luo Guanzhong's *Romance of the Three Kingdoms*, which, although set in the second and third centuries CE, spoke to contemporary political realities and aspirations.

Another literary revolution, actually a set of parallel revolutions, took place in the latitudinal extremes of Afro-Eurasia—Japan and Western Europe—where poets and prose writers broke cleanly away from the constraints of an inherited classical tradition and created new deeply expressive poems and stories in their vernacular tongues.

In Japan, where for centuries male scholars and poets had fashioned literary texts in Chinese that followed strictures set down in Tang China, a group of aristocratic women at the imperial court in Heian created Japan's first native literature. Not only did they write in Japanese,

but their work also displayed a range of imagination, emotion, and critical analysis beyond what was normally allowed by Chinese models. Around the year 1000 and shortly thereafter, two court ladies, apparently rivals and certainly opposites in personality, dominated this literary revolution and crafted works that became defining models of Japanese literature. Murasaki Shikibu (ca. 973–1025?) is generally regarded as the greater of the two. Her *Tale of Genji*, a work that has often been characterized, rightly or wrongly, as “the world’s first novel,” is a complex masterpiece of psychological insight. Equally probing in its ability to plumb the human psyche is her *Diary*, a highly polished work written for public consumption that does not shrink from revealing Madam Murasaki’s innermost thoughts, even her darkest ones. On the lighter side, the *Pillow Book* of Sei Shonagon (ca. 965–after 1000) is a collection of witty, often biting observations on life at the Heian court. Unlike Murasaki Shikibu, Sei Shonagon did not probe the darker side of the human psyche, but also unlike her rival, she did not keep secret her sexual life.

On the other side of Eurasia and more than a century later, Western European authors began to break away from the language and models inherited from classical Latin antiquity and write in their native tongues. The result was as liberating in Europe as it was in Japan. During a period that has been characterized by some as the “Twelfth-century Renaissance,” poets in the southern regions of the kingdom of France created a new lyric poetry in their native Provençal, whereas to the north writers of epics and chivalric romances were employing an equally flexible Old French as their medium. Influenced by these currents to their west, courtly *Minnesänger* (love poets) employed Middle High German for the same ends. Building upon these new movements but far exceeding them, Dante Alighieri (1265–1321) and Geoffrey Chaucer (ca. 1343–1400) almost singlehandedly transformed Italian and English into literary languages of great range and subtlety.

These three cultures—China, Japan, and western, or Latin, Europe—certainly had no monopoly on literary and dramatic creativity, as the entries under this topic illustrate. Indeed, as the entries and sidebars cumulatively bear witness,

the genius and imagination of bards around the world soared during these 500 years.

—Alfred J. Andrea

Persian Literature’s Golden Age

The Golden Age of Persian literature began in the ninth century on the eastern frontiers of the Abbasid caliphate. Earlier, Persian was the vernacular of the eastern part of the Islamic world but not a literary language, inasmuch as Arabic served as the dominant language of literature, law, and the caliph’s court. The ninth-century rise of Persian was partly due to the fact that by that time the Abbasid empire had become decentralized. In the Iranian and Central Asian provinces, local courts adopted Persian, and additionally many viewed it as a reassertion of their native Persian culture over a foreign Arab one. Patronage from the Samanid (819–999) court in Bukhara, in present-day Uzbekistan, and others in eastern Iran bolstered the awakening. Part of this renaissance included reviving pre-Islamic epics yet modifying them to respect Islamic sensibilities. As a result, former Sassanian artistic, political, and literary ideas found new life, even as Persian writers now wrote with the Arabic script and often incorporated elements, including vocabulary, from Arab and Islamic traditions. In addition to pre-Islamic stories being reintroduced, other themes became commonplace, such as wine poetry whereby poets discussed the virtues of wine yet also used wine as a metaphor to describe the intoxicating effects of God’s love, thereby making it often difficult to discern exactly the true meaning of the poem.

The Ghaznavid dynasty (975–1187) based in Afghanistan continued these efforts by patronizing Persian scholars and writers. Indeed, Ferdowsi (935–1020) presented the *Shahnama* (*Book of Kings*) to the greatest Ghaznavid ruler, Mahmud the Great (998–1030), in 1010. This epic, which became one of the most beloved, read, and lushly illustrated pieces of Persian literature, took Ferdowsi 30 years to complete and contains 60,000 verses. In addition to Ferdowsi, Mahmud also supported works on architecture and science. Samanid and Ghaznavid patronage led to a favoring of certain poetic forms such as the *ghazal*, a lyric poem of 7 to 15 couplets; the

➤ RASHID AL-DIN

Rashid al-Din Tabib (1247–1318), known to history as Rashid al-Din, was one of the chief ministers of the Il-khanid empire (1260–1335) and a polymath in addition to being one of the principal figures in the Golden Age of Persian literature. Born in Hamadan, Iran, to a Jewish family, he entered the court of the Il-khans as a physician and then rose to the office of chief *wazir* (vizier), or minister. During the reign of Ghazan Khan (r. 1295–1304), Rashid al-Din was among the most influential and powerful figures in the Islamic world.

Although Rashid al-Din ran the day-to-day affairs of the empire, he also proved to be an immensely talented scholar and writer and is often credited with writing the first universal world history. Ghazan Khan originally commissioned the work in order to preserve the history of the Mongols. Although the *Jamiat al-Tawarikh* (*Compendium of Chronicles*) focuses on the Mongol empire, Rashid al-Din also demonstrated considerable knowledge of other regions of the world far beyond the borders of any Mongol state. The work is invaluable as a historical resource, but it is also remarkable because it deviated from normal trends in medieval Persian histories. The writing style is simple and lucid rather than convoluted and poetic. Contrary to tradition, it is not interspersed with Arab poetry, or Quranic verses, to emphasize a point. The book was produced and lavishly illustrated in a workshop funded by Rashid al-Din, thus making it one of the more accessible medieval Persian works. He also compiled works on agriculture, medicine, and government.

—Timothy May

rubia, a quatrain; and the *masnavi*, or rhyming couplets used in fables, stories, and even histories.

During the centuries of Central Asian rule, Persian literature entered its Golden Age. Persian writers greatly influenced the courts of the Great Seljuk Turks, who in the eleventh century dominated most of the Middle East from Syria to Afghanistan. This was especially the case with the great vizier Nizam al-Mulk (1018–1092), whose guidebooks of advice on how to rule that he composed for these Seljuk sultans influenced the popularity of the Mirror genre. By the time

the Great Seljuk empire disintegrated in the late twelfth century, the Persian language and culture had permeated most aspects of court life. Thus, later Seljuk successor states, such as the sultanate of Rum located in Anatolia, used Persian in most of their official correspondence and record keeping, as well as patronizing Persian scholars and poets.

Indeed, it was in Konya, the capital of the sultanate of Rum (in present-day Turkey), that the greatest Sufi poet resided. Jalal al-Din Rumi (1207–1273) fled there as a child with his family from his home in Balkh, Afghanistan, just as the Mongols made their appearance in Central Asia. As he spent the majority of his life in Rum, he became immortalized as “Rumi.” He became a Sufi and eventually penned his masterpiece, the *Masnavi* (*Spiritual Couplets*), which, as the name indicates, is written in rhyming couplets. In this we see traditional Persian poetry motifs woven into Sufi thought, fables, and stories.

Most of the Islamic world was certain that the Mongols, whom Jalal al-Din’s family had fled, were God’s punishment for their sins as well as the greatest calamity to befall the earth since the flood. Oddly enough, the Mongols were crucial to the growth of the Golden Age of Persian literature. Many Persian literati fled to safer lands such as northern India, where many scholars, poets, and religious figures found refuge in the sultanate of Delhi. Indeed, combined with the traditions of patronage instituted from the Ghaznavid period, the Turkic Muslim elite of northern India now became thoroughly Persian in court and literary culture.

In addition to spreading Persian literature through refugees, the Mongols also brought stability to Iran, which had endured approximately 150 years of political disorder. In 1258, the Mongols destroyed the Abbasid caliphate with the sacking of Baghdad. While Sunnis mourned the loss of the titular leader of Islam, this act dramatically shifted the center of Islamic learning and creativity from Baghdad to a number of new centers. For the Arab world, Mamluk Cairo became the new center of culture, but farther east it was the many Turkic and Mongol courts, all of which were Persian in culture. The Il-khans of Persia, as the Mongol rulers of Southwest Asia were known, became crucial patrons of the arts,

as were many of the local dynasts who submitted to them. Indeed, during the Il-khanid period (1258–1335), there was truly a flowering of Persian literature unmatched in earlier centuries.

In the aftermath of the Il-khanid collapse, Timur-i Leng (ca. 1335–1405), known as Tamerlane in the West, arose. Although his name is synonymous with destruction, his capital at Samarqand (in present-day Uzbekistan) became a center of Persian culture, and his successors, the Timurids, who ruled until 1506, were among the most influential patrons of arts and science in the Islamic world.

Hafez (1325–1390), considered by many the greatest poet in Persian literature, lived and wrote his works in Shiraz, Iran, which Timur conquered in 1387. Although Hafez constantly ran afoul of the religious authorities for his sensual poetry and lifestyle, his poetry celebrated love for God as well as pleasure. He specialized in the *ghazal*, in which he wrote of everyday experiences in a style that avoided ornateness and artificiality. He also incorporated motifs from Sufism into his poetry, using erotic imagery to describe God's love. The last great Persian poet of the Golden Age was Jami (d. 1492) of Herat, in present-day Afghanistan, who quite unlike Hafez returned to using the ornate and stylistic forms of traditional Persian poetry. Jami also continued the practice of using Sufi motifs in erotic yet mystical poetry. The Timurids continued to patronize various poets and writers, but they also made substantial contributions in other ways.

A few of the Timurid rulers wrote poetry and other forms of literature. Furthermore, they helped establish Bukhara and Herat as centers of manuscript illustration and production, thus helping the spread and continuation of Persian literature.

The end of the Golden Age of Persian literature is generally considered around 1500, with the rise of the Safavid dynasty (1502–1736) centered in Iran. Although the Safavid court continued to patronize poets and writers, the militant and puritanical Shiism of the Safavids disapproved of Sufi-influenced metaphors of Golden Age poetry, whereby erotic imagery or the celebration of wine served as a means of describing the mystical experience. In general, while older forms of literature continued to be circulated,

very little innovation now entered into Persian literature.

South India's Performing Arts and Literature

The period 1000–1500, or more certainly the years around 1300 CE, witnessed the apogee of classical Indian civilization. During this period, royal patronage of the performing arts as a form of festival worship reached its peak, with artists performing before a specific deity at appointed hours during festival days.

Based on traditions that extended far back into antiquity, Indian performing arts were divided into dance, drama, and vocal and instrument music. According to tradition, these arts, which apparently originated in southern India's Tamil Nadu region, emerged from a sacred book known as the *Natya Sastram*, which tradition maintains that Brahma, the god of Creation, gave to the sage Bharatha, who thereby lent his name to *Bharatnatyam*, India's classic form of rhythmic dance. Available forms of this text mention that they were rewritten from an ancient treatise of the seventh century BCE.

An entire set of performing arts was prominently and exclusively developed from the *Natya Sastram* for temple worship. Its practitioners were considered to be servants of a particular god (normally Shiva or Vishnu), and their only profession was to sing, dance, and enact plays for that god without seeking any monetary gain. These art forms, along with the priests' chanting of the Vedas, performing vedic rituals, ringing

► THE PRIESTS OF CHIDAMBARAM

The origin of the priestly community that serves the Nataraja (Lord of the Dance) Temple in Chidambaram, Tamil Nadu is mired in legend and myth. Today the community numbers about 254 people (including family members), of whom about 100 officiate as priests. They are an endogamous community, meaning that marriages are confined within the community, and only a married man can become a priest. According to tradition, during the first epochal age called *Krita Yugam* (5 million years ago), Lord Shiva Nataraja blessed Chidambaram in the month of Thai (February–March) by choosing it as the site to provide a vision of the cosmic dance to a group that consisted of some sages whose pride he had tamed, various devas (gods), and two great devotees of his, one of which was Adi Seshan, the multiheaded cobra who serves as Lord Vishnu's couch and canopy, and Vyaghra Padar, a saint from Benaras. After this Lord Nataraja appointed 3,000 priests, who had accompanied him from his abode, to serve in the temple.

The current temple dates from at least the mid-first millennium CE, and various Chola monarchs, especially after 1000 CE, enriched, expanded, and fortified it, inasmuch as Shiva Nataraja was their dynasty's patron deity.

The priests follow an ancient system of ritual, worship, and temple duty, which has remained largely unchanged for nearly 2,000 years. They consider themselves to be the slaves, the keepers, the guardians, the devotees, and the worshippers of the Lord of the Cosmic Dance. Apart from Lord Nataraja and their worship of his anklet-girt (dancing feet), they have no existence of their own.

In the tumultuous period following the decline of their Chola patrons in the late thirteenth century, their numbers and fortunes declined precipitously, but never did they disappear totally or cease their temple services.

—K. Sethumadhaven

bells, anointing idols with sandalwood paste, and stringing flowers for bouquets, anklets, and corsages, were considered to be a service to the Almighty. The themes of these dances, plays, and music were usually taken from stories found in the Puranas (postvedic religious narratives), or the *Ramayana* and *Mahabharatha* epics, and

normally centered on the contest between the Almighty and evil.

Tamil literature dating back to the so-called Sangam period (ca. 600 BCE–500 CE) describes in great detail the various performing arts, emphasizing their finer points and nuances, the great expertise of its practitioners, and their meticulous observances of the rules governing their art. Two offshoots of the *Natya Satram* mentioned in the Sangam classics and that were prominent during the subsequent classical era were *Kutiyattam* and *Chakyar Koothu* (Chakyar Dance). The scripts of these dramatized dances were predominantly in Tamil and Sanskrit, but after 1500 many were translated into other vernacular tongues such as Malayalam, which is spoken in Kerala along the Malabar Coast. Both forms of dramatic dance are now designated as UNESCO world heritage arts.

Kutiyattam was and remains a dance drama form of worship centering on themes drawn from the *Ramayana*, the *Mahabharatha*, and the Puranas. Many inscriptions from the reigns of the eleventh-century Chola emperors Raja Raja the Great and Rajendra describe the performance of Kutiyattam temple plays during various annual festivals. The artists are said to have received a ration of rice and clothing on a yearly basis. Kutiyattam performances were accompanied by various drums and cymbals. Most of these instruments were also used as accompaniments for the singing of temple hymns.

Chakyar Koothu were/are dance dramas traditionally performed by the Chakyar community, an upper subcaste (*jati*) of religious performers whose members, as was true of Kutiyattam performers, lived in or around a temple and depended on it for their food and other sustenance. One form of Chakyar Koothu exclusively performed by women was (and is) *Nangyar Koothu*, narrative stories revolving around the life and exploits of Lord Krishna (an incarnation, or avatar, of Vishnu), which are transmitted by facial expressions, hand movements, and bodily gestures, all to the accompaniment of a drum.

Both Chakyar Koothu and Kutiyattam were strictly acts of worship and were staged in temple theatrical halls called *koothambalams* (*koothu* means “dance” or “drama,” and *ambalam* means “temple”).

The other form of dance drama also in vogue during this period was (and still is) known as *Ariya Koothu*, which probably had a connection with an ancient form of *kathak*, or storytelling. From an inscription of Aditya Karikala II (r. 950–965), we learn that this form of religious drama was also performed in temples by the Chakkayar community. Inscriptions further note that the seven acts of this play were to be performed every year, divided among the Tamil festivals of Thai Poosam, the feast of the Full Moon during February–March, and Margazhi Tiruvadira, a festival dedicated to the ascent of the star of the same name that was ascendant when the Lord Shiva shot a flaming arrow to destroy three evil cities. This latter festival is held during December–January. Their artists were entitled to a yearly stipend of cereals and clothing.

The use of musical instruments for worship is described in detail in many inscriptions of Uttama Chola (r. 965–984), and from those inscriptions it is possible to infer that the kind of temple ritual music prevalent then, when it was known as *Ksbetra Vadyam* (“temple music”), is still in vogue in the southern state of Kerala.

The rule of the powerful Chola/Pallava emperors also witnessed a great spurt in literary activity, especially in the Tamil language, but many or most of these works are no longer extant. As already noted, Sanskrit religious plays were composed during that period. Moreover, a spate of Saivite and Vaishnavite works (works dedicated to the worship of Shiva and Vishnu, respectively) in Tamil and Sanskrit were also produced during that period. The collection of hymns known as *Tiruthondar Tiruvandadi* (*The Story of Great Devotees*), compiled around the year 1000 by the Saivite saint Nambi Andar Nambi, and Sekkilar’s *Periya Puranam* (*Great Epic*), written around 1140, that recounts in Tamil the lives of 63 Saivite saints are some examples of the outpouring of religious literature during this fecund era.

Umapathi Sivacharyar, who lived in the Saivite pilgrimage city of Chidambaram in south-eastern India during the thirteenth century, was a great scholar of both Sanskrit and Tamil, and he has left behind several poetical narrative works in both languages, including the Tamil masterpieces *Siva Prakasam* (*The Light of Lord Shiva*), *Nenju Vidu Doothu* (*The Messenger Sent*

by the Heart), and *Vina Venpaa* (*Poetry in the Meter of Venpaa*). He also wrote a book on the history and significance of Chidambaram. Apart from these, he also authored several works in Sanskrit and also composed some Sanskrit *slokas* (two-line devotional verses) in praise of Lord Shiva.

Manikkavasagar, who lived in the Chola kingdom during the ninth century, may also be considered a product and literary artist of this period. His mystic *Tiru Vasagam* (*Dialogues with the Divine*) is a work of profound poetry whose verses, according to legend, were transcribed by Lord Shiva himself. These beloved poems are still memorized and sung all over contemporary southern India.

The last and most prominent of the 12 Vaishnavite *Alvars*, or early medieval Tamil saints of southern India devoted to the worship of Vishnu, was Nammalvar, who lived during the late ninth and early tenth century. He was to Vaishnava hymns what Raja Raja and Nambi Andar Nambi were to the hymns of the canonical Nayanmar saints of southern India who were devoted to the worship of Shiva. Nammalvar, also known as Sadagopan, not only composed 1,000 hymns, which he incorporated into the *Divya Prabandham* (*Divine Travelogues*) but also codified the works of previous great Alvar saints into the same collection.

Examples of courtly works are the *Kalingat-tupparani* (*Details of War in Kalinga*) by Jeyam Kondar, poet laureate of the Chola court who lived during the period of Kulothunga I Chola I (r. 1075–ca. 1115), and the *Muvarula* (*In Praise of the Three*) by the poet Ottakuttan, who lived at the court of Raja Raja II (r. 1046–1063), as well as that of other Chola monarchs. The former work details the two invasions of Kalinga by Kulothunga I; the latter is a poetic entertainment that praises the piety, physical strength, handsome appearance, ability to wield weapons of war, and conquests of three twelfth-century Chola emperors: Vikrama, Kulothunga II, and Raja Raja II. It should be noted that these works as we now have them might have been revised in subsequent ages, as is suggested by apparent anachronisms and erroneous details. A commentary on Tamil grammar called *Nannool* (*Collection of Strings*) by a Jain known as Bhavanandi,

who lived in the court of Amarabharanan (r. 1178–1192), a vassal chieftain to Chola emperor Kulothunga III (r. 1178–1213), is another work that has survived. Except for the authors of the above-mentioned devotional literature, we are ignorant of the reputations and standing of these authors of courtly and other secular literature as well as the significance of their work during their time of composition.

Many other now-lost works of merit might have been written of which we are now ignorant. Among the known lost works that scholars lament is the play *Tiru Rajarajeswaram Tiru Natakam* (*The Drama Surrounding the Building of Raja Rajeswaram*), a Tamil drama that told the story of the construction of a great temple at Tanjore by Raja Raja the Great.

In essence, so far as literary and dramatic production was concerned, the period 1000–1300 was more vibrant, eventful, and important than the eras that followed.

Performing Arts in China through the Early Ming Period

China has an ancient theatrical tradition. The combination of song, dance, costume, gesture, and representation by one person of another, or of a spirit or animal, goes back to very ancient shamanistic ceremonies, possibly as early as the third millennium BCE. Records and archaeological remains concerning proto-theatrical performances abound. Communal dancing for festival celebrations or other purposes, including the use of costumes and impersonation of animals,

dates back to the prehistoric period. Despite Confucian dictates that were highly critical of theater and, in particular, dance, these arts thrived. Many of the most ancient dynasties, from the Zhou on, had court offices overseeing performances connected to official ceremonies. Tang dynasty (618–907) emperor Xuanzong (a.k.a. Minghuang, r. 712–756) set up a music school in the Pear Garden (*Liyuan*) in his capital Chang'an. Actors today continue to be called “children of the Pear Garden.”

During the Tang dynasty, a genre of skits developed called *canjun xi*, distinctive for the role types of “adjutant” and “grey hawk.” These were actually the basis for many later comic types. During the Song dynasty (960–1279) and the alien Jin dynasty (1115–1234) of northern China, which expelled the Song to the south in 1126 but was itself overcome by the Mongols in 1234, *canjun xi* developed into a farce called *yuanben*, the term a contraction of *hangyuan zhiben* (literally, “scripts from the performers’ quarters”). Sometimes also called *zaju*, it flourished at all levels, from popular to court. Yuanben had several role types. Rather than just single items, there were music, dance, comic sketches, acrobatics, and slapstick. Central to it was a short comic play with a simple but identifiable story, and themes including love affairs, ghosts, gods, or demons. Costumes and properties were more complex than before, as were masks and makeup. A range of wind instruments and drums, as well as a plucked lute (*pipa*), provided music.

In the twelfth century, southern China enjoyed *nanxi*, a popular form based on folk song and with percussion only. In contrast to *yuanben*, these were stand-alone theatrical pieces. Because *nanxi* clearly included complex storylines showing a number of sophisticated theatrical conventions, some scholars regard it as China’s earliest drama form, the beginnings of *xiqu*. Although it declined when the Mongols took over southern China in 1279, it is the basis of many later southern forms, including *chuanqi* and *kunqu*.

Today, many regard the Yuan dynasty (1279–1368) as the “great age of Chinese drama.” Certainly, *zaju* was the most developed theatre yet produced. Although the music has not survived, the instrumentation suggests musical adaptation

into later styles. Beginning in the north, *zaju* spread all over China. During the late Yuan and early Ming (1368–1644) dynasties there was a revival of southern styles like *chuanqi* and from the sixteenth century the rise of *kunqu* and other regional styles.

Several Ming theatre features endured to the early twentieth century. One is the stronger differentiation into popular and aristocratic theatre, with *kunqu* the “elegant” drama of the educated classes and aristocracy while other regional styles are mass theatre. The higher classes owned private troupes, seen at banquets and special occasions. For the popular styles, venues were mainly temple stages, temporary stages in marketplaces, or any open space; performance occasions included fairs and festivals. In China, the actors’ low social status was legally confirmed through edicts. Discrimination against women was greatly strengthened, with male-only theatre companies becoming the norm, and most actresses being prostitutes. At court, the Ming set up a eunuch entertainment agency in 1390, which came to include drama, and from about 1740 the Qing trained eunuchs at court with the special duty of performing plays.

Christian and Islamic Universal Histories

As monotheistic religions that envisioned history as the stage upon which God’s Divine Plan for humanity was played out in a series of unique

moments that spanned the ages from Creation to the Last Judgment, both Christianity and Islam encouraged the writing of universal histories (i.e., the history of the world from Creation to the time of the author). Yet neither tradition produced that many, perhaps because of the intellectual and even psychological hurdles that would-be universal historians had to overcome. As seen in the few that were written, while they were superficially similar in approach and outlook, both the Christian and Muslim conceptions and expressions of universal history were, in fact, quite different.

The mold for Christian universal histories was found in the Bible. Accordingly, those medieval Christian historians who were bold enough to write universal histories focused their work on the moral lessons they could extract from history and subordinated their study of the past to the role of a didactic tool. The heart of their message was ethical monotheism, the notion that a single God of Infinite Goodness governs the universe and commands certain moral behavior of humanity. Within this framework history was linear, dynamic, and purposive, with a God-created beginning and a God-ordained end and goal. The significance of human events paled in the face of the moral implications of the Final Judgment.

The first Christian universal history is credited to a Greek bishop, Eusebius of Caesarea (ca. 260–339/340), the so-called Father of Church History whose ten-book *Church History* placed the trials and triumphs of the early Church down to his own day into the context of God’s providential plan for His people. In the Latin West, the two most influential early voices were Augustine of Hippo (354–430), a North African bishop, and his disciple Paulus Orosius (fl. 390–420). Augustine’s *City of God* (413–427), a rambling work of theology and not history, rejected the notion of human progress and postulated instead a sixfold division of an ever-degenerating human history, which however would end gloriously at the End of Time in the triumph of the City of God, a community of all who love God above self and reject the vanities of this world. Orosius’s *Seven Books against the Pagans* roughly popularized Augustine’s theology of

history by attempting to illustrate the miseries of human existence, especially before the Christian dispensation. Clearly, the problem with this sixfold division of human history (which paralleled the six “days” of creation) was that the sixth age—the current age that stretches from the life of Christ to his Second Coming—is an era of senility and increasing decay. This was poor incentive to write a universal history.

For all of the popularity of Eusebius and Augustine in later centuries and for all of the history writing that proliferated throughout Christendom, especially in the West after 1100, few Christian historians in the East or West had the intellectual confidence or learning to attempt a universal history. Notable exceptions were a German, Bishop Otto of Freising (ca. 1112–1158), and two Frenchmen, Friar Vincent of Beauvais (ca. 1190–ca. 1264) and his older contemporary Cardinal Jacques de Vitry (1160/1170–1240).

Otto’s *History of the Two Cities*, which he dedicated in 1157 to his nephew, Emperor Frederick I, traced the history of the world from Adam to 1146. Although Otto adopted the Augustinian schema of two cities—the heavenly City of God and the terrestrial City of Man—he departed from Augustine’s vision by tracing the progress in his own day of the earthly city. Undoubtedly he was influenced by the religious revivalism of his age as well as by the apparently successful Western empire carved out and governed by his nephew. A century later, the Christian West witnessed the flowering of encyclopaedists, one of whom was Vincent of Beauvais, a Dominican friar. Contained within his *Speculum universale* (*The Universal Mirror*), an attempt to present in systematic fashion the sum total of human knowledge, was the *Speculum historiale* (*The Mirror of History*), which presented in 31 books and 3,793 chapters a panoramic view of history from Adam to 1250 and the crusade of Louis IX of France. Between Otto and Vincent stood Jacques (James) of Vitry. His *History of the East* and *History of the West* (both completed ca. 1223 while he was bishop of Acre in the kingdom of Jerusalem), even when correctly considered as two parts of a single history, is not as sweeping in scope as the histories of Otto and Vincent, but the *History of the East* traces the vicissitudes of Jerusalem from the Old

Testament down to about 1210. Included in his treatment of the initial Muslim conquest of the Holy City in the seventh century is an account of Muhammad’s life and the doctrines of Islam.

Cardinal Jacques, himself a crusader, exemplifies the fact that most of the twelfth- and thirteenth-century Western historians of the crusades shared the visions and purposes of the writers of universal histories, even though their histories generally focused on relatively short periods of time. That is to say, they wrote to help make clear the workings of Divine Providence and Justice in human events and to encourage their coreligionists to lead lives that were consonant with that Divine Plan. Without a doubt, the greatest of these crusade historians was Archbishop William of Tyre (ca. 1130–1185/1186), a native-born Jerusalemite who was educated in Europe but returned to the East to serve the Church in the Latin kingdom of Jerusalem. Almost unique among Latin Christian historians because of his knowledge of Arabic and use of Islamic sources, William composed the massive *Jerusalem History* (also known as *A History of Deeds Done beyond the Sea*) that traced Christian-Islamic relations in the Holy Land from the seventh century to the late twelfth century. He also composed *The Deeds of the Eastern Princes*, which covered the period from Muhammad to 1184. Unfortunately, it is now lost. A critical historian who drew upon a wide variety of sources for his *Jerusalem History*, William did not hesitate to praise Muslims and condemn Christians when he deemed such judgments warranted. After all, for all of these Christian universal and semiuniversal historians, history was a divinely guided morality story.

To the contrary, in the Islamic world the primary focus of historical writing was not didactic. Rather, it provided a context for the prophetic career of Muhammad in its earliest phases and the success of the Muslim *umma* (community of believers) and their caliphs in later times. History writing therefore reflected the aims and ideas of the community rather being an attempt to modify or guide them. It is important to note that the majority of the earliest extant Islamic historical writing came from the mid-ninth and early tenth centuries, with one key exception. The historical accounts of the Prophet Muham-

mad's life and career appear toward the beginning of the ninth century, appearing in the form of redacted excerpts from earlier (now largely lost) sources. The key example of this style is the *Sirat Rasul Allah* (*The Biography of God's Messenger*) of Ibn Ishaq (d. 761). While the original work is lost, we possess extensive passages that were redacted by later historians, such as Ibn Hisham (d. 835) and al-Tabari (d. 923).

By the early ninth century, histories written about the Prophet began to have a definite pattern. Prophetic history was written with discrete sections: the *Kitab al-Mubtada* (*The Section, or Book, of the Beginning*, which deals with Arabia before the Prophet), the *Mabath* ("the sending," in this context, *God's Sending of the Prophet*), the *Maghazi* (*Raids and Battles of the Prophet*), and finally the *Tarikh al-Khulafa* (*History of the Caliphs*). In the case of Ibn Ishaq, his pre-Islamic section and his history of the caliphate are not extant; the only portions remaining are his sections on the life of Muhammad. It was in this way that the earliest Muslim histories were universal histories.

By the tenth century, this four-part segmentation of the early history of Islam began to break down. In its place, these divisions largely became separate genres in their own right. However, the notion of a universal approach was maintained. These works were not minor discursions. In the case of al-Tabari's *Tarikh al-Rusul wa al-Muluk* (*History of the Prophets and Kings*), which was the most influential of the Islamic universal histories, a span of 14,000 years is covered in roughly 8,000 pages, with the lion's share belonging to the development of the umma after Muhammad.

The difference between this work and previous universal histories shows the development of historical method in the Islamic world. The life of the Prophet Muhammad, previously represented in the aforementioned *Mabath* and *Maghazi* sections, merged into a new genre referred to as *Sirah* ("Biography") literature. This literature served as an important source of *hadith* (the Prophetic tradition), which had ritual implications for the community. History, for all its myriad of uses, could not claim to do this. As a result, Prophetic history diverged from other genres of history, became subject to rigorous in-

➤ RASHID AL-DIN TABIB'S UNIVERSAL HISTORY

The universal history of Rashid al-Din Tabib ranks among the great achievements in Persian literature from the period of the Il-khanate (1256–1336). The Mongol ruler Ghazan-Khan (r. 1295–1304), worrying that the Mongols were forgetting their roots, commissioned his vizier, Rashid al-Din, to write the history of the dynasty. However, upon Ghazan-Khan's death the next khan, Uljaytu (r. 1304–1315), ordered Rashid al-Din to expand it to include the histories of every people with whom the Mongols had come into contact. Thus, Rashid al-Din, with the aid of researchers and translators, began to write his history.

The work has four key sections: the Mongol and Turkish tribes from Chinggis Khan (d. 1227) to the death of Ghazan-Khan; a history of Uljaytu (now lost); a history from Creation to his day, including sections on the Arabs, Jews, Franks, and Chinese; and a geographical compendium (also lost). So dedicated to the preservation of this work was Rashid al-Din that he set aside money to have the serial segments of his work copied (in both Arabic and Persian) each year and sent out to various libraries. Additionally, an entire quarter of Tabriz, known as the *rabi Rashidi* (Rashid's quarter), was staffed with the most accomplished copyists and book binders to accomplish this task. Written on the finest paper and lavishly illustrated, these versions of the *Jami al-Tawarikh* were highly valued. However, when Rashid al-Din lost favor the project was halted, and time destroyed all but two copies made by this scriptorium. One extensive portion, with original illustrations, resides in Edinburgh; the other (an Arabic version of 120 pages) was sold at auction in 1980 for \$2,017,050, the highest price ever paid for an Arabic manuscript.

—Rasheed Hosein

terpretation, and was considered a science (*ilm*). History itself, other than Prophetic history, was not a science according to Islamic thought, and thus its practitioners began to focus on the *Tarikh* genre, a strictly narrative account of the vicissitudes of the umma, or community after 632. In the case of al-Tabari, his history had a simplified *Mubtada* and *Sirah* and an extended *Tarikh* section. This allowed for a more specialized approach. Since these Islamic histories reflected the

communities they chronicled, they took on political and sectarian aspects, leading inexorably to the Abbasid caliphs (750–1258) under whom the earliest of these works still extant were written.

The universal history as a genre did not end with the Abbasid fall in 1258. While political situations changed in the Islamic world, the notion of situating one's patron in the sweep of history remained valid. However, under Ibn Khaldun (d. 1406), the writing of universal history reached a level of sophistication that would not be rivaled until modern times in either Europe or the Islamic world. In the introduction (*Muqaddimah*) to his universal history known as the *Kitab al-Ibar* (*The Book of Evidence*), he not only set out to record a history since Creation but also set out to empirically explain the processes behind history, trying to describe the essential dynamic between the nomads and sedentary society and why dynasties fell after showing much promise at their inception.

The tenth century also marked an important change in the language in which history was written. Beginning with the Saffarid dynasty (fl. ninth century) and extending through the Samanid dynasty (875–999), Persian emerged again as a literary language in the eastern lands of the Islamic world. The great figures of this movement were the universal historians Ferdowsi (d. 1020), who wrote the *Shahnameh* (*Book of Kings*); Juvayni (d. 1283), who composed the *Tarikh-i Jaban Gushay-i* (*History of the World Conqueror*); and Rashid al-Din Tabib (d. 1318), author of the *Jami al-Tawarikh* (*The Collection or Compendium of Histories*). Within these texts, the notion of a separate Persia began to assert itself in distinction to the Arab-Islamic culture that had dominated since the conquest of the Iranian plateau by the Arabs in the seventh century. Under Ferdowsi, the poetry of pre-Islamic mythohistory and heritage emerged in the *Shahnameh*, wherein the stories of the great kings and military figures of pre-Islamic Persia became mirrors for young princes to emulate. While didactic in nature, the aim was political, not moral as in the Christian tradition. This work has been referred to as the “Persian Quran” by the great Kurdish historian Ibn al-Athir (d. 1233), who was himself writing a universal history in Arabic

under the title *Al-Kamil fi al-Tarikh* (*The Complete History*).

As exemplified by the work of Juvayni and Rashid al-Din, Islamic histories composed after the Mongol onslaught were exceptional examples of universal history. Rashid al-Din and, to a lesser extent, Juvayni wrote and lived in the largest contiguous empire ever created, linking Korea in the east to Poland in the west. Juvayni's history was ostensibly centered on the life of the great steppe conqueror Chinggis Khan (d. 1227) but was much more than that. Even though his history chronicled only the history of the peoples of Central Asia, including the Turks and Mongols, his work (according to Spuler) formed an important component in the universal Islamic history genre. More importantly, this history was seen as a landmark in Persian historical writing and served as a stylistic template for future writers. While stylistically well regarded, Rashid al-Din's *Jami al-Tawarikh* proved more noteworthy for its use of Chinese and European sources. Moreover, Rashid al-Din melded the Arabic tradition with the still-emerging Persian style and attempted to create the most complete world history ever attempted. For his efforts, Rashid al-Din is counted among the greatest Muslim historians.

The Transit of Proverb Literature— From Islam to the West

The Dicts and Sayings of the Philosophers, a compendium of heterogeneous philosophical lore attributed to classical and mythological sages, was the first book William Caxton produced after bringing the printing press to England in the mid-fifteenth century, but for the ultimate origins of this text we must look centuries earlier, to the Islamic world.

Dicts and Sayings and other works of wisdom literature (collections of proverbs and maxims) were among the many Islamic texts that passed through Muslim Spain and found their way into Christian Europe during the High Middle Ages. Even though these works were produced by non-Christian authors, they were welcomed by the West because clergymen and other elite Europeans approved their message of obedience to authority.

The roots of Islamic wisdom literature can be found in the intellectual renaissance that took place during the era of Harun al-Rashid (r. 786–809), the fifth Abbasid caliph. He and his son al-Mamun, known as Mamun the Great (r. 813–833), encouraged scholars to study the written work of earlier civilizations, including the Persians (who had been absorbed into the Muslim empire) and the Greeks. In 830 al-Mamun created the House of Wisdom, a college in Baghdad for the translation of Greek works into Arabic. The Greek language and literary tradition were unknown in most of Europe at this time, but here the study of Greek flourished; Greek philosophy, or *falsafa* in Arabic, was especially popular and formed the basis of Islamic philosophy. As in the West, Plato and Socrates were readily monotheized to make their teachings more consistent with religious doctrine. Aristotle, held in the highest esteem, was not so easily reconciled with Islam.

Generations of Muslim scholars sought to find the right balance between faith and *falsafa*. Al-Farabi (d. 950), for instance, demonstrated the consistency of Aristotelianism and faith while

THE DICTS AND SAYINGS OF THE PHILOSOPHERS

The following, a brief excerpt from *The Dicts and Sayings of the Philosophers*, is the beginning of the chapter on the sayings of the Athenian statesman Solon (ca. 630–ca. 560 BCE) and is typical of the prescriptive nature of this type of wisdom literature.

“Solon established the law in Athens and compiled many books of good sayings, and he was a resident of that city of Athens, which in those days was full of wise men. He made certain verses, by which he taught that a man should flee from his own willfulness. And he said: ‘When you do anything, do not follow your own will, but seek counsel, for by counsel you shall understand the truth of things.’ Some asked him a question: for what traits is a man most renowned? And he answered: ‘To know himself and to keep himself in safety, and not to speak in places where he should not speak, and to keep himself from anger . . . and not to covet the things that he cannot have.’”

maintaining the primacy of Islam. The famed physician Ibn Sina (980–1037), or Avicenna as he was known in the Latin West, made al-Farabi’s philosophies more canonically Islamic. And Ibn Rushd (1126–1198), or Averroës, argued that Islam and philosophy needed no reconciliation because they are separate spheres of truth that are not mutually exclusive.

In this intellectual climate arose a genre of literary works that collected philosophical wisdom in the form of pithy proverbs. *The Dicts and Sayings of the Philosophers* was one of the most ambitious. *Muhtar al-bikam* (*Chosen Sayings*), as it was titled in Arabic, was compiled by the eleventh-century writer Mubassschir ibn Fatik. Little is known for certain about the man or the exact body of sources he used. *Muhtar al-bikam*

presents, in roughly chronological order, the wisdom of such ancient thinkers as Pythagoras, Diogenes, and Socrates as well as a number of lengthy prose narratives about their lives and exploits.

The work's tour through Europe began when *Muhtar al-bikam* was translated into Castilian Spanish in the first half of the thirteenth century. The Spanish version was translated into Latin in the second half of that century, and its popularity throughout Europe is demonstrated by the vast number of manuscripts that survive. A few decades later the French courtier Guillaume de Tignonville (d. 1414) translated the Latin text into his native tongue and titled it *Dits Moraulx*. Guillaume's version reached English readers in the fourteenth century, and Chaucer's friend John Gower (ca. 1330–1408) used it as a source for his poetic masterpiece *Confessio Amantis* (*The Lover's Confession*). Chronicle writers, meanwhile, mined the work for anecdotes about the lives of philosophers. Several Englishmen translated *Dits Moraulx* in the mid-fifteenth century, and the translation by Earl Rivers was the one used by Caxton in 1477 as the first book ever printed in England.
